Atretium schistosum (olive keelback water snake)
Cerberus rhynchops (dog-faced water snake)
Natrix piscator (checkered keelback water snake)
Ptyas mucosus (Indian rat snake)

Family Elapidae:
Naja naja (Indian cobra)
Ophiophagus hannah (King cobra)

Family Viperidae:
Vipera rullellii (Russell's viper)

Vol. 49, No. 98, pp. 21089-21090. May 18, 1984. 50 CFR Part 17. Notice of Findings on Petitions Involving the **Yacare Caiman** and **Harter's Water Snake.** Comments may be submitted until further notice.

A petition to delist the yacare *(Caiman crocodylus yacare)* was received by the U.S.F.W.S. on December 27, 1983. The species has been listed as endangered since 1970; it is native to Argentina, Brazil, Bolivia, and Paraguay. The Service has concluded that the petition does not present credible, substantial biological or commercial data to warrant a delisting at this time.

A petition to list the Harter's water snake *(Nerodia harteri)* as threatened with critical habitat was received by the Service on February 28, 1984. The finding states that the petition does contain substantial biological data that a listing may be warranted. The species is known only from central Texas. The Service is soliciting data on: Taxonomy, distribution, critical habitat, and threats.

Other Conservation Issues of Note:

The Secretariat of CITES issued a notice (No. 300) on 30 May 1984 that The Government of the Republic of Bolivia has established a total ban on export of live wild animals from all its territories, effective 1 May 1984 until 1 May 1985. The Secretariat reminded parties that Brazil and Paraguay has established an indefinite ban on the export of all wild animals. Peru has adopted stricter domestic measures and is authorizing the export of only a limited range of species of psittacidae.

The first draft of a Habitat Conservation Plan for the **Coachella Valley fringe-toed lizard** *(Uma inornata)* was completed in April as a cooperative venture between the U.S.F.W.S., the Nature Conservancy, and affected local governments. For further details, see Endangered Species Technical Bulletin IX(5):2.

The seventh season of protection and conservation for **Kemp's ridley sea turtles** *(Lepidochelys kempii)* at the Playa de Rancho Nuevo breeding beaches in Mexico began this year. As of April 26, 50 nests had been protected (Endangered Species Technical Bulletin IX(5):3).

The U.S.F.W.S. and NMFS have withdrawn their proposal to allow transshipment of certain **green sea turtle** *(Chelonia mydas)* products through the port of Miami, Florida. The European Economic Community on January 1, 1984, restricted trade in green sea turtle products with western European nations, thereby making the ruling unnecessary. (See FR 4/26/84, or End. Sp. Tech. Bull. IX(5):10).

U.S.F.W.S. "box scores" of listed species indicate that there are currently 96 species of reptiles and 16 species of amphibians currently listed as endangered or threatened either in the U.S. and/or in foreign countries. Recovery plans have been prepared for eight species (8.3%) of reptiles and three species (18.8%) of amphibians. By contrast, there are approved recovery plans for 19 (6.5%) of the 291 listed mammals, 41 (19.3%) of the 212 listed birds, 26 (45.6%) of the 57 listed fishes, 13 (26%) of the 50 listed invertebrates, and 21 (28.4%) of the 74 listed plants. Total: 795 listed species with 131 species (16.5%) having approved recovery plans.

(Although some of the notices printed in this column are "outdated," we feel it is important to call them to the attention of the herpetological community. We welcome contributions of significant—though outdated—notices from SSAR members.)

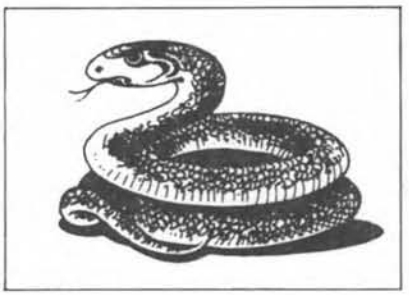
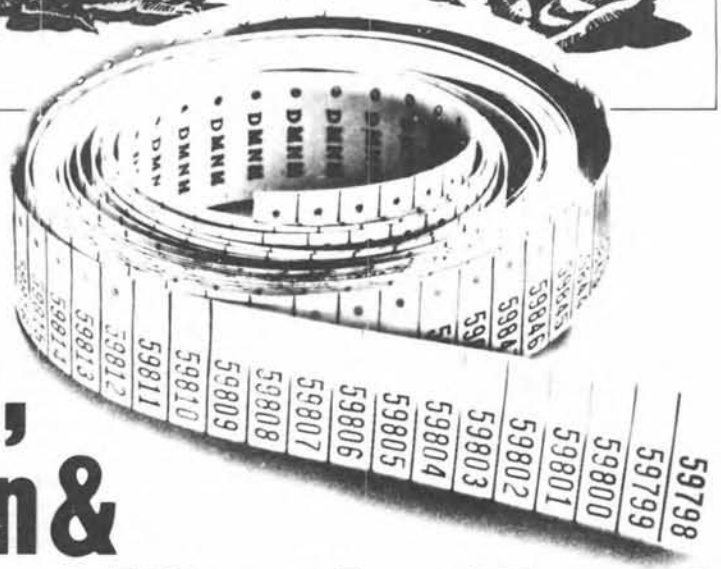
NEWSNOTES



THIRD EDITION OF THE *CODE*

The International Commission on Zoological Nomenclature has indicated that the 3rd edition of the International Code of Zoological Nomenclature will soon be available. The book consists of parallel English and French texts, totaling about 320 pages (216 mm x 318 mm). It will be for sale for 15 pounds, plus 1.50 pound for postage and handling, through the Publications Sale, British Museum (Natural History), Cromwell Road, London SW7 5BD England. Individuals and organizations may also purchase it for $21.50, postage and handling included, by writing:

American Association for
Zoological Nomenclature
Room W-115
National Museum of Natural History
Washington, D.C. 20560, U.S.A.



In order that the Code will be widely available, a prepublication price of $18.75, postage and handling included, for individuals is in effect until March 31, 1985. Delivery of the Code will be in Spring, 1985. Checks drawn on a United States bank or International Money Orders should accompany all U.S. orders! Please make checks payable to American Association for Zoological Nomenclature. ●

Either stock or custom made.

Need Reptile, Amphibian & Specimen Identification Tags?

Order them here and now.

Stop your searching. Here are those identification tags you've been looking for. Save time, money and patience simply by ordering them right now from the NATIONAL TAG COMPANY. Use this page as your order form.

Non-soluble and waterproof inks • Special 10-pt. stock impervious to solvents • Alcohol and formalin proof • Pre-punched • Consecutively numbered* • Rolls of 2M • 1-week delivery • Custom tags take slightly longer but can be printed on both sides.

*Note: Stock tags are consecutively numbered, but the starting number will vary for each shipment. There's no printing on back side. Custom tags can get any numbering sequence desired, with or without prefix letters, plus printing on the back side (illustration above).

NATIONAL TAG COMPANY, 815 S. Brown School Rd., Vandalia, OH 45377

LIST OF ENDANGERED AND THREATENED SPECIES

A new, comprehensive list of endangered and threatened wildlife and plants, updated through 20 July 1984, is now available. This new version, published by the U.S. Fish and Wildlife Service, contains a section on those species that have been removed from the list since 1973. Copies of the free list can be requested from:

SOCIETIES

SPRING ESHL MEETING

The Spring meeting of the Eastern Seabord Herpetological League will be held on Saturday, 9 March 1985 at the Harvard University Science Center, Cambridge, Massachusetts. The meeting will be hosted by the Massachusetts Herpetological Society and will consist of a series of presentations on a variety of topics in herpetology. All interested individuals are invited to attend.

ESHL is a consortium of thirteen regional herpetological societies (Connecticut, Georgia, Lehigh Valley, Maryland, Massachusetts, New York, North Carolina, Philadelphia, Virginia and Washington Herpetological Societies, and The Association for the Conservation of Turtles and Tortoises, NOAH, and Turtle Trust) which meets each March and October for a series of paper presentations. All members of the constituent societies may attend the meetings, for which there is no registration fee.

Further information about the March 1985 meeting may be obtained from Joe Martinez (617) 846-8321 or Dorothy DeLisle (617) 698-2601.

Further information about the Eastern Seaboard Herpetological League may be obtained from:

Raymond Logue, ESHL Coordinator

THE BOMBAY NATURAL HISTORY SOCIETY: SOME RECENT PUBLICATIONS

In the fall of 1983 the Bombay Natural History Society celebrated its one hundredth anniversary. Founded initially by an enthusiastic and devoted band of amateurs, both British and from the local community, it soon expanded its horizons. Today it is the preeminent privately funded research association in India with members in all states, as well as most foreign countries, and research projects proceeding across the subcontinent. The Society has published a number of books, most notably the extensive studies of Salim Ali and Dillon Ripley on birds of the subcontinent.

Its journal, the **JOURNAL OF THE BOMBAY NATURAL HISTORY SOCIETY,** is now in its 81st volume, each current volume including approximately 800 pages of technical papers per volume, whereas the more slickly presented **HORNBILL** presents popular articles on this or that animal or adventure.

During 1983, the Society published several items of interest to our membership. The first was an anniversary issue of the **HORNBILL,** marking the centenary and including some substantial and historical information regarding its activities and those of its scientific staff and associates. The next is **A CENTURY OF NATURAL HISTORY,** a collected series of articles excerpted from the **JOURNAL** and assembled by topics with historical vignettes of the authors. The 78 articles include coverage of herpetology, specifically three herpetological papers, namely Malcolm Smith on monitor lizards, Asana on *Calotes* and F. Wall on snakes. Beyond the directly zoological interest, the 755 page well-illustrated volume contains such nuggets of biological information as the amount of game killed by the Mogul emperors (documenting their interest in zoology!), detailed descriptions of elephant capture and specific instructions on mahseer fishing.

Of more specific interest to the herpetological audience is J. C. Daniel's **BOOK OF INDIAN REPTILES,** representing the first complete coverage of the topic since Malcolm Smith's volumes on the Fauna of British India on which the present treatment heavily relies. The volume includes accounts of the Indian genera of reptiles and for these summarizes many of the short notes published in the **JOURNAL.** The list is selective and for many genera, only a single species is described. It is illustrated with new photographs of turtles and crocodilians as well as of the more common species of lizards. For the snakes, the volume reprints the beautiful and well reproduced color drawings initially published in the **JOURNAL** by the late Frank Wall. Whereas this book does not represent a taxonomic advance over the earlier volume (for which, although reprinted several times, the snake account is again unavailable), it provides a useful, quick guide to the fauna.

It should be noted that the prices of both these volumes are most reasonable at $12.50 and $7.50 (substantial members discount to $9.00 and $6.00), respectively. As the annual membership dues including subscription to the **HORNBILL** and the **JOURNAL** are only $16.00 (plus a $2.50 entrance fee for the first year), this would seem to be a good way of adding to one's library while simultaneously supporting an extremely worthwhile organization. The address of the Society is Hornbill House, Shahid Bhagat Singh Road, 400023 Bombay, India.

THE DELAWARE HERPETOLOGICAL SOCIETY

A new Herpetological society has formed in Delaware. Even though the society is just a few months old, we have a large number of interested people attending our meetings and hope to expand in the near future. A newsletter is published monthly—the first newsletter was issued in September 1984. Meetings are held monthly, upon notice, at the Ashland Nature Center, Hockessin, Delaware.

Membership includes newsletters, participation in and notification of trips, reptile and amphibian shows, and other events sponsored by the society. Anyone interested in reptiles and amphibians is invited to join.

Further information about the Society may be obtained by contacting John LaMedica, President, (302) 453-9754, or Susan Moreau, Treasurer, (302) 322-6827.

DHS would like to exchange with other herpetological societies. Our mailing address is:

MEETINGS

REPORT ON THE 1984 AUSTRALASIAN HERPETOLOGICAL CONFERENCE, AND 1984 ANNUAL GENERAL MEETING OF THE AUSTRALIAN SOCIETY OF HERPETOLOGISTS HELD AT SYDNEY AND SPRINGWOOD, 28 AUGUST TO 2 SEPTEMBER 1984

Herpetology in Australia, New Zealand and the Pacific islands is a small but vigorous discipline. Its practitioners recently gathered in Sydney, on an unprecedented scale (approximately 180 participants), to discuss diverse aspects of their work.

The 1984 Australasian Herpetological Conference may best be appreciated in the light of its forerunners. For many years, the Aus-

tralian Society of Herpetologists (A.S.H.) has held general meetings at intervals of about 15 months. More recently (1980), Chris Banks organized a Herpetological Conference in Melbourne, to which interested amateurs as well as professional scientists were invited. The response was very encouraging: the papers were good, the discussion lively, and the Proceedings published (Banks and Martin 1982).

The success of the Melbourne meeting stimulated ideas of a second Conference, this time on a larger scale, to be held in association with the "annual" meeting of A.S.H. in the Sydney area in 1984. The Conference was jointly sponsored by the Royal Zoological Society of New South Wales, the Australian Museum, A.S.H., and Taronga Zoo. The Organizing Committee (Gordon Grigg, Rick Shine, Harry Ehmann) appointed chairmen for a series of symposia which formed the main part of the meeting. The symposium topics (and chairmen) were as follows:

Population Ecology (Hal Heatwole)
Physiological Ecology (Gordon Grigg)
Ecological Biogeography (Hal Cogger)
Reproduction and Development (Col Limpus)
Phylogeny of Elapid Snakes (Terry Schwaner)
Husbandry and Captive Breeding (Chris Banks, Terry Boylan)
Rare and Endangered Species (Mike Tyler)
Chromosomes and Evolution (Max King)

Almost 100 papers were presented, and approximately 180 people registered for the Conference. Carl Gans delivered the keynote address "In Praise of Diversity," and showed erotic films of tuataras coupling. Several other American colleagues who have worked extensively on Australian animals (e.g. John Legler on chelid turtles, Sam McDowell on elapid snakes) also attended the meeting, but most participants came from Australia and New Zealand, with two from Fiji. All states of Australia were represented.

It is difficult to identify highlights of such a diverse meeting. The papers presented were generally of very high standard, and most of the symposia provided a comprehensive picture of recent developments in the field of interest, by the major Australian workers in those fields. In many cases, recent work has radically altered and expanded our understanding of the herpetofauna. Perhaps the most obvious example of this increase in knowledge, and diversification of methodologies, came from the most specialized symposium: that on the phylogenetic relationships of Australasian elapid snakes. The affinities of species within this group have proven difficult to resolve by use of conventional morphological data, but contributions from all of the major workers in this field showed strikingly concordant results from data on immunology, microcomplement fixation, electrophoresis, karyology, venom structure, internal anatomy, ecology, and the use of external morphological characters not previously considered. The conclusion that emerges is of a relatively recent adaptive radiation, with many of the viviparous genera sharing a very recent common origin.

The Conference was held primarily at the University of Sydney, but with some events at the Australian Museum and Taronga Zoo. The Conference Proceedings will be published in early 1985 by Surrey Beatty Ltd., and are being edited by Grigg, Shine and Ehmann. Following the end of the Conference on 31 August, approximately 80 of the participants travelled to Springwood, in the Blue Mountains west of Sydney, for the A.S.H. "annual" general meeting. The papers and festivities continued for another two days. Again, the standard of presentations was high, as was the enthusiasm of the audience—despite the scientific and social rigours of the previous week. Menna Jones, from the University of New England, won the Student Prize for her paper on water relations of agamid eggs. Brian Weavers, of the Australian National University, was awarded a book prize for his presentation on thermoregulation of varanid lizards.

The Business Meeting was a more torrid affair than is usual. Having disposed of routine business, planned for the next A.S.H. meeting (in Armidale in December 1985), and elected office-bearers for 1985 (President - Gordon Grigg; Vice-President - Rick Shine; Secretary-Treasurer - Gillie Courtice; Assistant Secretary-Treasurer - Arthur White; Public Officer and Editor - Ric Longmore; Councillor - John Coventry), the meeting turned to a more controversial issue: the recent publication of a checklist of Australian reptiles in a privately edited journal (Wells and Wellington, *Aust. J. Herp.* 1, numbers 3-4, 1983) which proposed massive nomenclatural changes. One of the authors of this article (Wells) also is the editor of the journal in which the article appeared. The three scientific members of the journal's editorial board present (Max King, Hal Heatwole, Jeff Miller) noted that they had not reviewed the article in question, and that they had now resigned from any involvement with the journal because of the publication of the checklist.

The meeting then passed a series of motions, summarized below:

1. that A.S.H., representing professional herpetologists in Australia, has no association with the "Australian Journal of Herpetology";
2. that the society reaffirms its commitment to peer review, and to adherence to the rules and recommendations of the International Code of Zoological Nomenclature;
3. that the society will apply to the International Commission to suppress the publication entitled "A synopsis of the Class Reptilia in Australia" in the "Australian Journal of Herpetology" Volume 1, Nos. 3-4.

The submission for suppression of this checklist is now being prepared by officers of the Society, who would be grateful for comments or advice from any members of the international herpetological community.

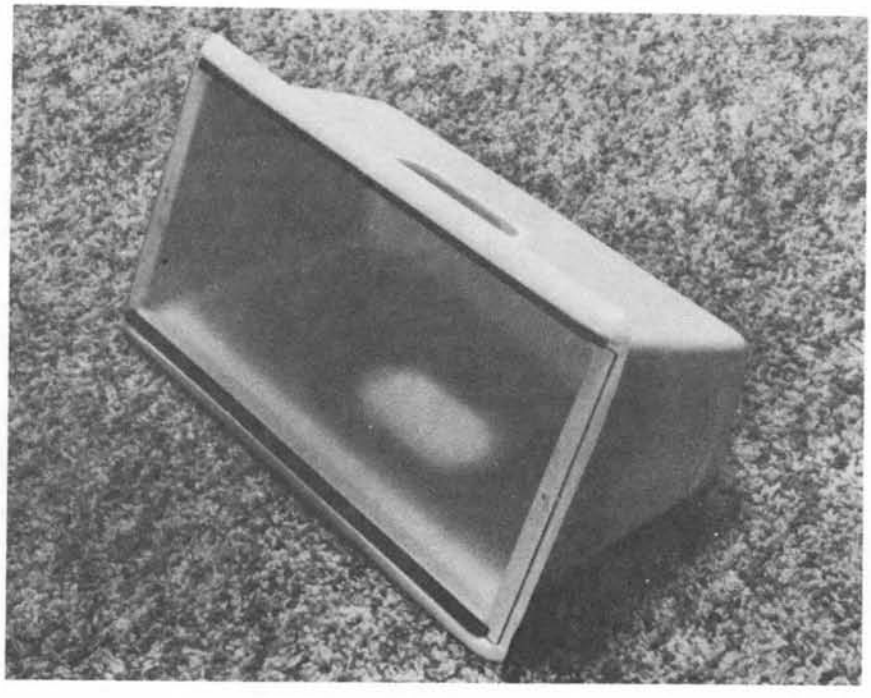
REVIEW OF BONN SYMPOSIUM ON AFRICAN VERTEBRATES

An International Symposium on Systematics, Phylogeny and Evolutionary Ecology of African Vertebrates was held May 15-18, 1984 in Bonn, Federal Republic of Germany, to commemorate the 50th anniversary of the opening of the public exhibits of the Zoologisches Forschungsinstitut and Museum Alexander Koenig. Forty contributors from 14 countries presented papers. The travel expenses of the invited participants were reimbursed in part by a grant from the German Science Foundation. Karl-L. Schuchmann, Ph.D., Assistant Curator of Ornithology organized the symposium. Herpetologists who participated in the symposium, and the titles of their presentations, were:

Ulrich Joger. The African Gekkonine radiation—preliminary results on evolution and historical biogeography. (Bonn, F. R. Germany)

Barry Hughes. A systematic review of African Green Snakes of the genus *Philthamnus*. (Accrah, Ghana)



E. Buffetaut. Zoogeographic history of African crocodilians since the Triassic. (Paris, France)

Wolfgang Boehme. Zoogeographical patterns of the herpetofauna of the African Subsaharan savannah belt. (Bonn, F. R. Germany)

Hartwig Berger Dell'Mour. Transition from normal to serpentiform appearance in the South African genus *Tetradactylus* Merrem, Gerrhosauridae, Sauria. (Windhoek, Namibia)

Jens Rasmussen. The retinas of some boigine snakes including a discussion of some

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $29.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $53.95

36" Wide, 18" High, 19" Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

MASSASAUGA RATTLESNAKE SYMPOSIUM

Preliminary steps are underway to organize an Eastern States symposium on the massasauga rattlesnake. The scheduled dates are 15 & 16 August 1985. The location will be the Jennings Environmental Education Center in Butler County, Pennsylvania.

Anyone interested in presenting research, status reports, or other pertinent information should submit a brief proposal to the address below. Some stipend money will be available to defer speakers' costs.

Due to the sensitive nature of the data being reviewed, the acceptance of symposium participants will be made by a panel. Please include a brief resumé when sending for additional information to:

ANNOUNCING THE NINTH INTERNATIONAL HERPETOLOGICAL SYMPOSIUM on CAPTIVE PROPAGATION & HUSBANDRY at San Diego, California June 26-30, 1985

CALL FOR PAPERS

All herpetologists are invited to submit for consideration the titles of papers they wish to present at the 9th International Symposium on Captive Propagation and Husbandry to be held at the University of San Diego in San Diego, California. A pre-day to the conference will take place at the Roeding Park Zoo in Fresno, California on June 25, 1985. Paper lengths may range from 20-40 minutes. A preliminary program will be established by April, 1985 so a 100-150 word abstract of a presentation should be submitted by contributors prior to 1 April 1985. *Titles should be submitted as soon as possible.* Final manuscripts should be submitted prior to 15 June 1985. Submit all program information to: Sean McKeown, Curator of Reptiles, Program Chairperson, Roeding Park Zoo, 894 West Belmont Avenue, Fresno, California 93728; (209) 488-1096. ●

REPTILE CAGES

Designed with your needs in mind.

Desirable features of Herp-Huts:

- Should never have to be replaced.
- Molded in one piece of durable fiberglass, no seams, all corners rounded.
- Smooth finish facilitates easy cleaning and sterilization.
- Top front ridge, ideal for clamping heat lamp, if desired.
- Two vented louvers per cage (standard), designed to prevent scratches to animals and entrance of flies. Side or top mount possible.
- Side mounted vent plates make top/bottom interchangeable, creating pitch alternatives.
- Sloping front for easy viewing.
- Special vertical ridges on either side of cages "A" & "B" minimize possibility of small snakes getting wedged or escaping.
- Design suitable for reptile houses, mobile reptile exhibits, and reserve cages.
- ★ **Newest Option:** Feature requested - Hingeable front door with or without 5 inch safety glass shield.
- Traditional sliding glass front accessibity.

A New Approach to an Old Concept

★ *Newest Option: Hingeable Door* ★

Custom Orders Also

HERPETOLOGY IN AUSTRALIA

Although the land area of Australia is similar to that of the U.S., with a correspondingly large and diverse herpetofauna, we have a much smaller population of scientists to study these animals. Hence, a great deal of Australian herpetology is concerned with taxonomy (many new taxa are described each year) and basic natural history. Increasingly, however, detailed studies on ecology, physiology, and other aspects of particular species are being carried out.

The major scientific society is the Australian Society of Herpetologists, with a membership of approximately 200. The A.S.H. holds annual general meetings, usually of two to three days duration, of the same format (but rather different scale) as the American meetings. A newsletter is produced on an irregular basis. Membership is open to all publishing herpetologists: information is available from the Secretary (Dr. G. Courtice, School of Physiology, University of New South Wales, Kensington, Sydney, N.S.W.).

The most recent A.S.H. meeting was held at the beginning of September 1984, in conjunction with the 1984 Australasian Herpetological Conference in Sydney. Overseas scientists are welcome at both meetings, and the Conferences provide an excellent opportunity to meet many of the herpetologists working in Australia. Proposed symposia included biogeography, physiological ecology, population ecology, conservation, reproduction, phylogeny and biochemical systematics.

Further information on the published proceedings of the conference is available from:

PREHISTORIC OCCURRENCE OF THE REDBELLY TURTLE *(Pseudemys rubriventris)* AT CONCORD, MIDDLESEX COUNTY, MASSACHUSETTS

The current range of the redbelly turtle *(Pseudemys rubriventris)* in Massachusetts is extremely limited, encompassing a few ponds in Plymouth County and possibly Ipswich, Essex County (Graham 1982; U.S. Fish and Wildlife Service 1981). Statements that *rubriventris* may also exist on Naushon Island, Dukes County (Lazell 1976; U.S. Fish and Wildlife Service 1981) have been questioned by Graham (1982), who excludes Naushon from the present range. The prehistoric range of *rubriventris* also encompassed Ipswich as well as Martha's Vineyard, Dukes County, where finds have been made of Indian midden specimens (Bullen 1949; Waters 1962, 1966, 1969; Lazell 1976; Graham 1982).

Waters (1962) theorized that the Massachusetts population of *rubriventris* was an isolated remnant of a widely distributed coastal *rubriventris* population extending from Virginia in the south to Massachusetts in the north. He further theorized that the disjunct Massachusetts population had become increasingly restricted through prehistoric extirpation due to human predation. Based on the above evidence and theoretical considerations, Waters (1962), Lazell (1976), and U.S. Fish and Wildlife Service (1981) have concluded that *rubriventris* may have been widespread in eastern Massachusetts in prehistoric times. Further data to delineate the extent of this range are clearly needed.

We recently examined bone fragments from prehistoric Concord Shell Heap, an Indian midden located on the Sudbury River at Route 2, Concord, Middlesex County, Massachusetts. The site and its remains were originally described by Smith (1940) who reported finding 571 turtle fragments, which, however, he did not attempt to identify. Careful re-examination of Smith's material reveals the presence of 683 turtle fragments. Of these, 63 can readily be identified as representing *rubriventris*. The fragments reported on here are currently in the collection of the Concord Antiquarian Museum, number 19MD388 (M33-18).

Among the 63 fragments several can be pieced together to form series from individual animals. The most complete is a 5-bone set comprising neurals 3 through 6 with a portion of the right 6th costal. The midline length from N3 to N6 in this specimen is 104.8 mm, which corresponds to a large individual of approximately 300 mm carapace length (based on comparative measurements of 4 whole adult *rubriventris* shells from the Museum of Comparative Zoology, Harvard University). Also present are the right 8th through 10th marginals of a large individual as well as the left 11th marginal and pygal bones from 2 large individuals. Two pieces from a single large nuchal are present, as are 6 additional separate marginal bone fragments. In addition, there are two pieces each from the left 6th and 8th costals of two individuals, one large and one rather small, as well as 32 other costal fragments. Additionally, there are 2 fragments from the left xiphiplastron and one right xiphiplastron from 2 large individuals, as well as 4 other plastron fragments. Based on our analysis of these fragments, there were at least 3 individual *rubriventris* in the Concord Shell Heap (2 large and one smaller).

None of the fragments of *rubriventris* show signs of having been worked by prehistoric people, and many of them are fire-charred. In all probability, therefore, these animals were collected locally for consumption and were not obtained via inter-tribal trade (see Bleakney 1958; Adler 1968, 1970).

These findings establish the presence of *rubriventris* in Concord in prehistoric times, ca. 80 km to the northwest of Plymouth and ca. 55 km to the southwest of Ipswich. They also lend further support to the theory that *rubriventris* formerly inhabited a wider area in eastern Massachusetts and that it may have become extirpated at least partially through the activity of prehistoric man.

ACKNOWLEDGMENTS

We thank Dennis A. Fiori, Director of the Concord Antiquarian Museum for making the materials available to us for study. We also thank Shirley Blancke, Russell Barber, Richard Meadow, and Jose Rosado for assistance.

NESTING AND EGG LAYING BEHAVIOUR OF THE GARDEN LIZARD *(Calotes versicolor)*

The common Indian garden lizard *Calotes versicolor* has drawn the attention of a number of workers (Asana 1931; McCann 1937; Mulherkar 1962; Singh and Thapliyal 1962; Thapliyal and Singh 1962; Pandha and Thapliyal 1964a, b, 1967; Minton 1966), who described different aspects of its natural history, but nesting and egg laying behaviour have not been reported. The present paper presents observations made on a nesting female in the village Sanbalisai, Midnapore, West Bengal, India in June 1980.

During a study of amphibious snails beside paddy fields the authors saw a female *Calotes versicolor* descending a nearby mango tree at 0515 hrs on 23 June 1980. The lizard started digging a hole on the ground about 40 cm away from the tree. The soil was moist due to a shower the preceding night. The lizard made a round hole containing no loose soil by removing soil with the forelimbs or, occasionally, with the hindlimbs. The digging operation lasted for 17 minutes. The lizard did not move for about 6 minutes but surveyed its surroundings continuously. At 0538 hrs, the lizard positioned itself with the genital aperture above the center of the hole, at which point it started laying eggs. After laying 5 eggs, the lizard moved and arranged the eggs in the hole using both fore and hind limbs. This was followed by a second and third laying after which the egg arranging was repeated. After the fourth laying the female did not arrange the eggs and started pushing the soil over them. The hole was filled up to the level of the surrounding ground. The number of eggs in the second, third and fourth laying could not be counted as close approach might scare away the lizard. The lizard remained motionless for some time and then quickly moved up the same tree. The whole operation took 26 minutes.

The covering soil was carefully removed from the nest with a brush. The eggs were 18 in number, white in colour, oval to elliptical in shape, soft shelled and measured 11.0 x 6.8 to 14.5 x 9.0 mm, the average being 13.1 x 7.9 mm. The diameter and the depth of the nest were 4.5 cm and 6.3 cm respectively.

It appears that in West Bengal *C. versicolor* lay eggs in rainy season, i.e. from late June to August as has been reported by Asana (1931), McCann (1937) and Pandha and Thapliyal (1967) from other parts of India. The reported incubation period is 40 to 47 days (Pandha and Thapliyal 1967). Eggs are laid immediately or shortly after heavy monsoon has set in, presumably to escape desiccation of the embryos during incubation. This also ensures abundant supply of food to the young lizards, since the number of insects and other animals on which they feed are abundant in this period. No report is available on the time of egg laying of *C. versicolor*. Egg laying in early morning is probably an attempt to escape predators such as crows *(Corvus splendens)* and foxes *(Vulpes bengalensis)*.

DEATH-FEIGNING IN THE GRAY-BANDED KINGSNAKE *Lampropeltis alterna*

Death-feigning (letisimulation) has been reported for a number of snake genera (see reviews by Gehlbach 1970; Carpenter and Ferguson 1977) but not for kingsnakes, genus *Lampropeltis*.

On 28 May 1973, one of us (RKG) came upon an adult female *Lampropeltis alterna* on the road after dark 16 km W Lajitas, Presidio County, Texas. The snake was first seen in the headlights of the car with a ringtail cat *(Basseriscus astutus)* standing over it. The cat ran off the road as the car came to a halt but the snake remained motionless. It was initially assumed that the specimen had been struck by a car though no obvious injury could be detected, and that the cat was scavenging a road kill.

The specimen was limp throughout examination and did not attempt to right itself when placed on its back. After a minute or two, the specimen was placed in a semi-coiled position in the car and driving commenced. Approximately 10 minutes later the specimen was noted to be missing from the seat. Several minutes of searching revealed it actively crawling through the springs under the seat. At this time it appeared totally active and uninjured, and was later placed in the collection of the Dallas Zoo where successful reproduction occurred in later years. Similar behavior was not subsequently seen in this specimen.

On 30 August 1979, a group of eight neonate *L. alterna* was routinely weighed and measured one day after hatching. After being measured, one specimen became limp with neck slightly crooked and mouth slightly agape. When left undisturbed, the specimen slowly righted itself and began crawling normally. When touched, it quickly assumed the death-feigning position. This result was obtained several times in succession. Rough handling after the initial episode, however, failed to produce similar behavior.

In September 1980, a group of 18 hatchlings of this species was utilized to determine if this type of behavior could again be elicited through human handling. Each was placed on a carpet and tapped with a flat hand several times, once crawling began. Through repeated trials, specimens defecated and often coiled loosely and remained motionless with heads tucked beneath or between body coils, and began crawling a few seconds to several minutes after harassment was discontinued. None, however, exhibited feigning type behavior.

We feel that the death-feigning noted in two isolated instances could have been induced by odors or other stimuli from "natural" (versus "unnatural") predators. *L. alterna*, being almost entirely nocturnal, would be instinctively cautious of predatory mammals, such as *B. astutus*, and these predators represent a "natural" threat to this species whereas man may not. What caused one of the neonates to react in this manner is unknown, but since the squeeze-type measuring box had been used for numerous other species of young snakes, including *L. getulus holbrooki*, perhaps this was also induced by odors from "natural" predators.

The presence of death-feigning behavior in *L. alterna* after exposure to these types of stimuli but never, at least as far as is known, to that from man (an "unnatural" predator) during collection or harassment leads us to believe that death-feigning may only be elicited in some species under conditions not normally observed by man. Further, it is probable that this behavior may be partially or entirely dependent upon olfactory cues rather than physical harassment in some species. Another interpretation is that death-feigning in some species is a polymorphic behavioral trait, possessed only by some individuals. Additional research using a variety of "natural" and "unnatural" predator odors may eventually bear this out.

We thank Martin J. Rosenberg for his helpful comments on the manuscript.

TECHNIQUES

NOOSE TUBE: A LIGHTWEIGHT, STURDY, AND PORTABLE SNAKE RESTRAINING APPARATUS FOR FIELD AND LABORATORY USE

Restraining apparatuses for venomous reptiles for purposes of handling and study have employed a variety of designs. Such devices have three principal functions: the safety of the investigator, the safety of the animal, and the safe handling of the latter while under restraint. Restraining devices designed for lab use can be large, complex, and time consuming to use. Field use requires compactness, sturdiness, simplicity, and the potential for rapid deployment. Ideally, such apparatuses should be usable by one investigator. MacDonald (1964) describes taping the reptile to a wooden dowel of slightly larger diameter than the animal. Murphy (1971) used a graded diameter series of tubes into which animals are coaxed. Another device uses troughs and "L" shaped boards onto which animals are placed and then restrained with nooses or velcro straps (Luck and Keeler 1929, Ward and Harrell 1978). Gillingham (1983) recently discussed an immobilization technique using a five gallon plastic pail. Freed and Freed (1983) described an apparatus for venomous snakes that employs freezer containers to restrain the head in a hole in the lid.

Although these apparatuses have utility in a variety of situations, they also have some constraints. The device described herein (which we term a "noose tube"), is practical in the field or lab for sexing and marking animals—especially venomous snakes, for making length measurements, minor and major surgical manipulations, heart puncture, venom collection, administration of drugs, and almost any "hands on" procedure (see Figs. 1 and 2).

Our apparatus is inexpensive, simple to use, and is easy to make or modify. Materials consist of a two inch (5 cm) diameter Lexan® tube, 18 to 24 inches (46-60 cm) in length (General Electric Corp., 1 Plastics Ave., Pittsfield, Mass. 01201), 0.375-inch (1 cm) aluminum tubing, 0.062 inch (2° mm) nylon cord and cord clamp, one large cork stopper "#12 (6 cm, top diameter)," two automotive hose clamps, one to fit each of the tubes, and two leather straps eight inches (20 cm) in length (Fig. 3). The cork is bored with a hole large enough to allow smooth movement of the aluminum tube and is inserted in one end of the Lexan® tube. When so constructed, the

Figure 1. Nylon cord loop being placed around a prairie rattlesnake's neck. Note that the investigator can remain a safe distance away from the serpent.

inner tube slides easily. The cork is then secured in place with leather straps, one on each side of the hole, and the large hose clamp. The nylon cord is doubled over forming a loop and fed through the aluminum tube, and about 20 cm of the loop should be exposed at the bottom of the tube. The free ends of the cord are placed in the cord clamps and then knotted so that the clamp may slide toward the tubing for tightening.

The apparatus is now ready for use (Figs. 1 and 2). Tether an animal by placing the loop over the animal's head and drawing the cord snugly around the animal's neck. The snake may then he held in place by moving the cord clamp down to the aluminum tube. The skull structure of most venomous snakes prevents escape, so the cord should be secure but need not be too tight. Some practice on the part of the investigator or user is a must in order to become familiar with the device. The clear Lexan® tubing allows for easy monitoring of the subject even when the animal is placed shallowly into the apparatus. The investigator can now expose as much of the snake as is required for the procedure.

This device has proven quite useful in both lab and field applications, on thousands of

Figure 2. A prairie rattlesnake safely restrained within the apparatus.

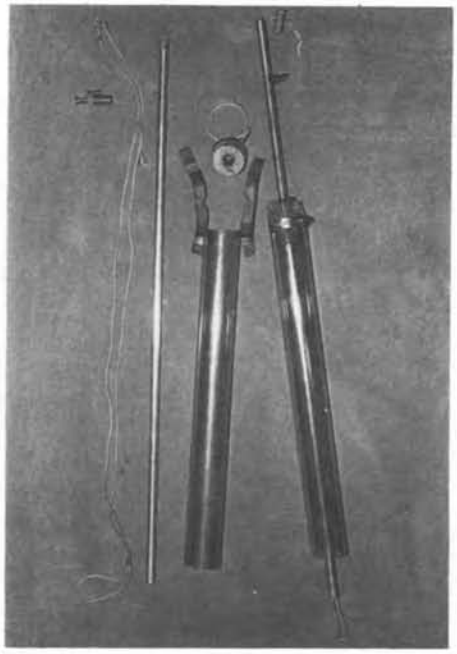

Figure 3. One assembled and one unassembled unit (showing the former's component parts), as described in the text.

snakes. Never once has an animal been hurt or overly stressed while restrained with this device. We think other investigators will find this apparatus to be efficacious and useful.

A QUICK, EASY AND PERMANENT TAGGING TECHNIQUE FOR RATTLESNAKES

Numerous visual and isotopic tagging techniques for snakes have been published (Blanchard and Finster 1933; Conant 1948; Woodbury 1948, 1956; Pendelton 1956; Hirth 1966; Hirth et al. 1969; Weary 1969; Pough 1970; Bennion and Parker 1976; Brown and Parker 1976a,b; Parker 1976; Fitch and Jacob 1981; Sanders and Jacob 1981). However, literature pertaining to tagging rattlesnakes in particular is limited (Fitch and Glading 1947; Pough 1966; Clark 1971; Pendelbury 1972; Lewke 1974; Klauber 1956). This paper presents a quick, easy and permanent tagging technique for rattlesnakes.

Fine stainless steel wire (B and S 30, 000 Steel, Monofilament Type B), coloured spangles (sequins) 0.5 cm (3/16 inch) in diameter, and "5 Minute Epoxy" were used for tagging. Each rattlesnake was restrained using the technique described by Almandarz (1978). One spangle (metallic pink for females; metallic light blue for males) was threaded onto a short piece of stainless steel wire. Each rattlesnake was identified (numbered) according to a (letraset) number stenciled on the spangle. The first female (and male) tagged had a spangle numbered 1. Females (and males) tagged thereafter had spangle numbers which increased sequentially. The wire was twisted together between the proximal rattle segment and the body of the rattlesnake making sure the spangle was placed flush against the lateral (widest) side of the rattle. The spangle and wire were then covered with a thin layer of epoxy.

This technique allowed an immediate sexing of tagged rattlesnakes in the field without handling. Sex identification was easily made at 15 m with the naked eye, even when rattlesnakes were in the coiled position. If individual identification was required, a closer examination of the spangle was necessary by use of binoculars or by physically restraining the snake. Since the epoxy dries clear, stenciled numbers on the spangles were protected and visible on close examination. Positioning a spangle on the side of a rattle prevented excessive wear when the rattle dragged on the ground. The "Five Minute Epoxy" provided a permanent fastening of a spangle and wire, preventing snagging in the wild and possible removal. Removal is only possible if the rattle breaks off anterior to the tag.

Tagged rattlesnakes displayed no apparent problems with ecdysis and there was no infection. The location of the spangle during subsequent captures can provide information on the number of shed cycles since the initial tagging. The writer used this technique to tag 23 prairie rattlesnakes. Marked specimens have been sighted a total of 16 times since April 1983.

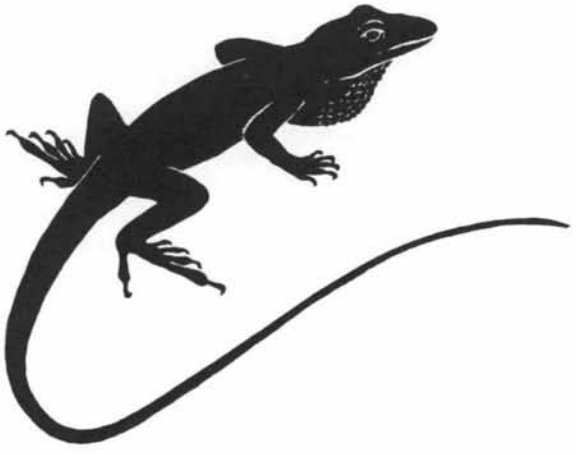
LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.



ANURA

RANA PALUSTRIS (Pickerel Frog). **OVIPOSITION.** On 10 March 1984 a large female pickerel frog was seen depositing eggs in Donaldson's Cave, Lawrence County, Indiana in a slow moving stream with an average depth of about 6 cm but with several pools up to 25 cm in depth. The female was laying the eggs on an old glove submerged in one such pool. The site of oviposition was about 50 m from the entrance in total darkness. An estimated 100-200 eggs had been laid when the observation was terminated. Fourteen additional frogs were counted, but no vocalizations were heard or other eggs seen. Two cave salamanders *(Eurycea lucifuga)*, cave crickets, and spiders were seen in the vicinity. Air temperature in the cave was 14° C.

The association of pickerel frogs with caves in Kentucky, Tennessee, and the Ozarks was emphasized by Schaaf and Smith (1970. Her-

SAURIA

ANOLIS CAROLINENSIS (Green Anole). **INTERBREEDING.** Seven varieties of exotic anoles are known to have established breeding populations in the Miami area (Wilson & Porras, The Ecological Impact of Man on South Florida Herpetofauna, 1983). *Anolis sagrei sagrei* (brown anole) is naturalized from Cuba and was first reported in the United States from the Florida Keys (Garman 1887). It is now well-established throughout much of peninsular Florida and the Florida Keys and is now the most abundant lizard in urban areas of southern Florida. It has already displaced the native *A. carolinensis* in many areas of Florida through heavy competition for food and habitat.

A male *Anolis carolinensis* was observed copulating with a female *Anolis sagrei* (brown anole) in Goulds, Dade County, Florida on 12 October 1983. The female escaped capture after separating, and no juvenile anoles showing signs of hybridization have been observed in the vicinity. Interbreeding between *A. carolinensis* and *A. sagrai* is previously undocumented, and the possibility of hybridization between exotic anoles and *A. carolinensis* suggests that populations of the latter may be further threatened in areas of sympatry.

SERPENTES

BOIGA CYANEA (Green Cat-eye Snake). **ENVENOMATION.** Some viperid snakes are affected by their own venom, and there are many reports of fatal conspecific or self-inflicted bites (Pope 1955. **Snakes Alive,** 161-162; Bellairs 1970. **Life of Reptiles,** (2)517). However, there appear to be no reports of conspecific envenomation by rear-fanged colubrids. This note reports such a case.

On 28 April 1984, while feeding two *B. cyanea* housed in the same cage, a 120 cm snake struck a 155 cm snake about 2 cm behind the head while chasing a mouse. The attacker held on to its cage-mate for several minutes before they were separated. The larger snake became lethargic two hours after the bite. This muscular weakness increased over the next two days and the snake died 30 hours after having been bitten. No other symptoms were noted.

Submitted by **HAROLD F. DE LISLE,** P.O. Box 292, North Hollywood, California 91603, U.S.A. ●

CALLOSELASMA RHODOSTOMA (Malayan pit viper). **FEEDING MIMICRY.** Luring potential prey by tail movements has not been reported in *C. rhodostoma.* The diet of free-ranging *C. rhodostoma* includes species which are susceptible to luring (Blody 1983. Herp. Review 14:74). On several occasions from spring 1983 to late summer 1983, I observed a captive juvenile (S-V length, 292 mm; tail length, 36 mm) female *C. rhodostoma* exhibit tail movements similar to those used by related species for luring potential prey. Typically the entire tail was held vertically and would undulate slowly. Large arc movements of the tail were not observed. The specimen was always stationary and did not flick its tongue. The presence of food (newborn mice or frogs) was not necessary to stimulate the tail movements. Evidence that the tail movements could lure potential prey was obtained on 25 August 1983. At 2030 h the specimen initiated tail movements within minutes after a young *Rana pipiens* was placed in its cage. The frog oriented toward the moving tail, hopped to it, and was struck, killed and consumed. The frog was struck before it could bite the tail. Luring was observed several times following this observation, but it terminated by late summer, by which time the tail was increasing in gray coloration.

The specimen died 3 March 1984 of accidental causes. It is deposited at UMMZ (176879). Its S-V length is 351 mm; tail length is 42 mm.

It has been suggested elsewhere (Schuett et al. 1984. Anim. Behav. 32:625-626) that the term "feeding mimicry" is more appropriate than the term "aggressive mimicry."

COLUBER CONSTRICTOR MORMON (Western Yellow-belly Racer). **BEHAVIOR.** Aggressive or combat behavior among snakes of the same species is well documented (DeLisle 1978. Herpetology 10:8-14; Shaw 1951. Herpetologica 7:149-168; Shine 1978. Oecologica 3:269-277). Combat behavior in snakes usually is observed in captive specimens, most frequently crotalids (Carpenter 1979. Copeia 638-642; Carpenter et al. 1976. Copeia 764-780; Lindsey 1979. Herp. Review 10:93). This behavior has also been observed in a number of colubrid genera (generally in captivity), including *Elaphe* (Gillingham 1980. Herpetologica. 36:120-127.), *Masticophis* (Hammerson 1978. J. Herp. 12:253-255.), and *Lampropeltis* (Carpenter and Gillingham 1977. S.W. Nat. 22:517-524.). We report here on aggressive behavior of *Coluber constrictor mormon* observed in the wild.

On 9 June 1983, in a small limestone canyon near the Colorado-Utah border in Dinosaur National Monument (Uintah Co., Utah) we observed two *C. c. mormon* struggling with each other. The temperature was about 22-25° C with fair weather.

The snakes, 55 and 60 cm long, were on a wide ledge about 30 m from a small stream in the bottom of the canyon. The dorsal portion of each snake's head was contained in the mouth of the other, to such a depth that the eyes of neither snake were readily visible. The snakes were juxtaposed dorso-ventrally to obtain this mutual attachment. At least the anterior portion of one of the snakes always was on its back (Fig. 1).

Figure 1. Dorsal-ventral attachment of struggling *Coluber constrictor mormon.* (Photograph courtesy of RME Photographics.)

After about 10 min, the smaller snake weakened, but it did not appear that the larger snake could extricate itself from the smaller snake's mouth nor could it swallow the smaller snake because the latter's mouth contained the dorsal portion of the larger snake's head. It appeared that neither of the snakes would survive the confrontation, so we carefully separated them and released them about 50 m apart. Because of the weakened conditions of the snakes and our presence in a national monument, we minimized handling and therefore did not determine their sex prior to their release. After about 10-15 minutes, both snakes departed without any noticeable adverse effects from their encounter.

Competition for food, mates, territory, and dominance have been offered as explanations for combative behavior (Carpenter and Gillingham 1977. S.W. Nat. 22:517-524.). Because of the mortal nature of the combat observed here, mutual consumption appears to be the motivation. Fitch (1982. *In* Herp. Comm. USDI, FWS Res. Rep. 13. 83-97.) reported that in northeastern Kansas, almost 2% of the prey items for *C. constrictor* were its own kind. However, Brown and Parker (1982. *In* Herp. Comm. USDI, FWS res. Rep. 13. 59-81.) found that in northern Utah only 1% of the prey items for *C. constrictor* were snakes, represented only by *Masticophis taeniatus.*

We found a third *C. c. mormon* within 2 m of the previous two. We could not determine the sex of this snake since it avoided capture. Even though we did not observe the behavior of the snakes as the confrontation was initiated, locating 3 mature *C. c. mormon* in such close proximity, with two of them in combat, suggests that this behavior was probably an interaction not associated with capturing prey.

NAJA MELANOLEUCA (Forest Cobra). **COPROPHAGY.** On 29 October 1983 a *Naja melanoleuca* was observed to deliberately ingest fresh fecal material. It is not known whether the feces were from the snake in question or from one of the other three specimens in the exhibit. This behavior was observed for almost 10 min after which the snake moved to another section of the display. The same snake had been observed with fecal matter in its mouth on the morning of 22 October but was not seen to swallow it. At that time it was assumed that the snake had picked up the feces accidentally during foraging. A further instance of coprophagy was observed on 30 December 1983.

No eggs, newly-hatched young or shed skins were in the exhibit on any of the three occasions so there seems little likelihood of the behavior being linked with reports of keratophagy (Groves 1977. SSAR Herp. Review 8(4):124) or post-parturient ingestion of dead young/fetal membranes (Groves 1980. Brit. J. Herp. 6(3):89-91) in snakes. The snake had also never been fed on reptiles or amphibians while in the collection and, to the best of my knowledge not before that time either, as she was captive-bred. On this basis the observed behavior would appear to be a quirk, possibly induced by captivity.

Although a number of lizard genera, particularly herbivorous iguanids (Groves 1983. Per. comm.; Troyer 1982. Science 216:540-542), are known to be coprophagic, I have been able to locate only one reference to such behavior in snakes (Peterson 1980. SSAR Herp. Review 11(1):9). This was a single observation of a female *Thamnophis s. sirtalis* eating its own feces immediately after defecation. I have also been advised that a *Notechis scutatus* at Houston Zoo ingested fecal matter on a number of occasions, including one instance of consuming two or three paper towels presumably because they held the odor of fresh feces. These were later regurgitated (Tryon 1984. Pers. comm.).

The assistance of John Groves and Bern Tryon in obtaining reference material is gratefully acknowledged.

THAMNOPHIS ELEGANS VAGRANS (Wandering Garter Snake). **COLORATION.** Melanistic *Thamnophis elegans vagrans* are known from western Washington and eastern Oregon but not from elsewhere in the Pacific Northwest (Nussbaum, Brodie, and Storm. 1982. Amphibians and Reptiles of the Pacific Northwest). We collected five melanistic individuals of *T. e. vagrans* from the Grand Rhond River valley in southeastern Washington. Two of these snakes were collected on the river bank in June of 1978 approximately 10.5 km S of Anatone, Asotin Co., WA. The three other individuals were collected in 1981, 15 km SW of Anatone, Asotin Co., WA. These five snakes plus two more that were observed but not captured represent 35% of the twenty *T. e. vagrans* observed at these sites. All of the melanistic snakes were collected on the rocky shore or in the water. Snout-vent lengths ranged from 272 to 570 mm and masses

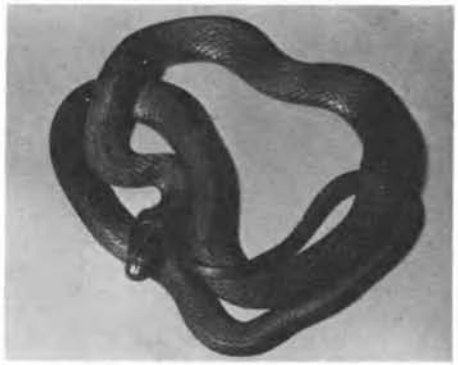

Figure 1. A melanistic male *Thamnophis elegans vagrans* (568 mm SVL). Asotin Co., Washington. The background is an 18% reflectance Kodak gray card.

ranged from 8 to 67 g. Both males and females were collected. The dorsal surfaces of these individuals are very dark but the spaces between some of the dorsal scales (visible when the body is distended) are light and a faint pattern is discernible (Figure 1). This pattern has become slightly more prominent during captivity. The ventral surface is dark blue except under the chin, which is a lighter blue grey color. To quantify the melanism, we measured the reflectances of the dorsal surfaces of melanistic and normally colored *T. e. vagrans* in Warren Porter's laboratory at the University of Wisconsin, Madison. The overall reflectances (290 - 2600 nm) were 6% and 16% for the melanistic and normal individuals, respectively. The reflectances in the visible range (400 - 700 nm) were 1.5 and 12.5%, respectively. The overall and visible reflectances of basalt (the most common substrate from the banks of the river) were 6% and 5%, respectively. These snakes have been kept alive for breeding experiments and ultimately will be deposited with the Field Museum of Natural History in Chicago, Illinois.

TESTUDINES

DERMOCHELYS CORIACEA (Leatherback sea turtle). **MIGRATION.** Although leatherbacks have been tagged on nesting beaches in several parts of the world, few long-distance recoveries of tagged individuals have been reported. This, along with the peculiar foraging habits of leatherbacks, with some individuals feeding in shallow littoral waters and others following pelagic jellyfish into high latitudes, has hampered efforts to discover the migratory routes of the various populations. The low rate of recovery is presumably due to the pelagic habitat preference of the species, to a particularly high rate of tag loss, and to the dearth of fisheries exploiting this species. Meylan (1982, pp. 91-100 *In:* Biology and Conservation of Sea Turtles, Smithsonian Institution Press) reviewed published records of long-distance recoveries on a worldwide basis, as of 1979. Of these, only seven recovered turtles were leatherbacks that had been tagged in the Caribbean. Two additional long-distance recoveries within the Caribbean, both involving stranded turtles, have been reported (Eckert and Eckert 1982. Rept. to U.S. Fish and Wildlife Service; Lambie 1983. Marine Turtle Newsletter, 24).

This note reports the recapture of a leatherback turtle tagged after nesting at Tortuguero, Costa Rica, on 11 July 1979, and captured at sea 23 August 1983, off the south coast of Cuba. The capture (method unknown) was made by the crew of a commercial fishing vessel near Isla Blanco (21°38'N, 79°53'W), a small cay 15 km SE of the port of Casilda. The minimum straightline distance between these localities is 1315 km. This leatherback is one of only three that have been tagged at Tortuguero during the course of a 28-year tagging project that has focused on the green turtle *(Chelonia mydas).* The tag was of monel metal, size #49 (National Band and Tag Company, Newport, Kentucky, U.S.A.). The recovery represents a retention time of slightly over four years.

PSEUDEMYS NELSONI (Florida red-bellied turtle) **BEHAVIOR.** Male aggression toward conspecific females in the genus *Pseudemys* has rarely been documented, although it has been seen in many other turtle genera (Jackson and Davis 1972. Herpetologica 28:58-64). The following observations were made with a mask, snorkle and wetsuit in Rock Springs run, Apopka, Florida, about 1 km downstream from the springs and at the site of an ongoing behavioral study of *P. nelsoni* and *P. floridana.* The incidents occurred on 27 and 30 Dec. 1983 after a very hard freeze. During these periods of observation the water temperature was about 21° C and the air temperature, about 18° C. The two incidents totalled 30 min of the 14.5 h spent underwater observing turtles in December.

In the first incident (1709-1732 h), I observed a female *P. nelsoni* which appeared to be resting on the bottom, approximately 1 m below the surface and below the fronds of a fallen palmetto floating at the surface. The mud bottom had been stirred up and at least six min passed before I realized that a male *P. nelsoni*, covered with mud, had the female's right front foot grasped in its jaws. Neither turtle appeared to respond to my presence. This was unusual as most turtles in the run initially orient towards me when sighted underwater. Nine min after I first saw the female, the male dragged her around in a small semicircle, resulting in the pair turning 180 degrees. During this sequence, I distinctly heard the shells clattering together caused either by the female's attempt to free her foreleg, rapidly repeating extension and retraction of the male's neck, or a combination of the two. I estimate that a clattering bout lasted 3-5 s and included 5-15 individual knocks.

The female then dragged the male upstream about 60 cm. A min later another male *P. nelsoni* swam to the female and perched on top of her carapace, with his neck fully extended and his head arched down. There was little movement for three min, then the first male, still grasping the female's leg, started jerking on it. The ensuing motion dislodged the second male, which swam slowly about the pair. The turtles' activity further stirred up the bottom and limited visibility but two bouts of clattering were heard in about 2 min. The second male left the area and five more bouts of clattering were heard in the following six min. The first male released the female, which swam in a semicircle and then upstream. Upon releasing the female, the male swam to the surface and breathed rapidly. I found the female about eight m upstream resting on the bottom, apparently unharmed.

The second incident (approx. 1630-1637 h) was much like the first and occurred about 15 m away. Although I could not ascertain the identity of the male, the females in the two incidents were different individuals. Before the female was released, there were seven bouts of shell clattering in approximately seven min.

The significance of these interactions is not known. The only observation of courting behavior in *P. nelsoni* is given by Jackson (1977. J. Herpetol. 11:221-222). He found active female participation but no agonistic behavior. There is, however, a marked similarity between the behavioral sequences described above and those observed by Davis and Jackson (1973. Herpetologica 29:62-64) describing the courtship of a male *P. scripta taylori*. Jackson and Davis (1972. op. cit.) suggest that biting during courtship is primitive in *Pseudemys* and, due to sympatry with other members of the genus, has been replaced in *P. scripta elegans* by a species-specific ritual. There is no reason to presume that all of the sympatric species have lost the biting act. In *P. nelsoni*, biting and shell-clattering may have become ritualized and necessary as a precursor to successful copulation.

TERRAPENE CAROLINA CAROLINA (Eastern Box Turtle). **MORPHOLOGY AND BEHAVIOR.** A tiny *Terrapene carolina carolina* retained a rigid plastron and never developed a hinge throughout the four months of its captivity although its shell increased 20 per cent in length. This animal could only be induced to eat small earthworms, which were most readily accepted when the turtle was allowed to swallow them under 8 mm of water in a petri dish. The turtle (Michigan State University Museum, Herpetology Number 13000) was collected on the campus of Shorter College, Rome, Floyd County, Georgia, 2 May 1982. It measured 28.0 mm in carapacial length when it was caught, and 33.5 mm (cl) when it died suddenly from unknown causes, 8 December 1982. As far as I can determine, adult *Terrapene carolina* have not been reported to feed under water.

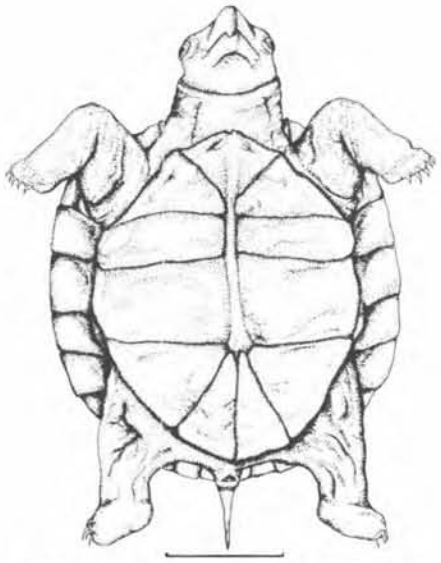

Figure 1. *Terrapene carolina carolina* (MSU-H-13000) from Rome, Floyd County, Georgia, in ventral view; drawn May 23, 1982. A hinge is missing and the plastron is immovable. The line equals 10 mm.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

CAUDATA

DICAMPTODON COPEI (Cope's Giant Salamander). USA: WASHINGTON: Lewis Co: T14N R8E Sec. 22, 9.0 km N, 8.3 km W Packwood, in a tributary of Skate Creek, off Skate Creek Road. 28 April 1984. Lawrence L. C. Jones. Verified by D. B. Wake and S. K. Sessions. Museum of Vertebrate Zoology, University of California, Berkeley (MVZ 187688). Represents the northernmost locality in the Cascade Mountains, extending the known range 35 km NE of Quartz Creek locality (Nussbaum. 1976. Misc. Publ. Mus. Zool., Univ. Mich. 149:1-94). This larval or neotenic specimen was taken below a waterfall at a depth of 15 cm. Contribution No. 18 of the Old-growth Forest Wildlife Habitats Program, USDA Forest Service.

NEW HERPETOLOGICAL RECORDS FROM ARIZONA NORTH OF THE GRAND CANYON

During the last 4 years, personnel of the Department of the Interior Bureau of Land Management, Arizona Strip district, and the Arizona Game and Fish Department have collected the following species in the northwestern corner of Arizona. Specimens are deposited in the Los Angeles County Museum of Natural History (LACM); identifications were verified by Robert L. Bezy.

HYLA REGILLA (Pacific Treefrog). USA: ARIZONA: Mohave Co: Middle Spring, 9 km SE Virgin Peak; T36N, R16W, SE Sec. 7, 1295 m. 25 May 1983. M. Serena. LACM 136195-99. Extends range approximately 28 km E (A. P. Blair, 1955, Amer. Mus. Novit. 1722:17-38: "*Hyla regilla* . . . found calling in chorus with *B. woodhousei* in the lower Virgin drainage.").

PHRYNOSOMA DOUGLASSII HERNANDESI (Mountain Short-horned Lizard). USA: ARIZONA: Mohave Co: 5 km SE Snap Point. T32N, R14W, NW Sec. 26, 1900 m. 4 June 1983. D. Roderick. LACM 136194. Extends range 95 km S (Stebbins, R. C. 1966. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston).

DIADOPHIS PUNCTATUS REGALIS (Regal Ringneck Snake). USA: ARIZONA: Mohave Co: Figure 4 Canyon, Virgin Mts., 1330 m. 26 April 1983. D. Smith. LACM 136192. Extends range 30 km SW (Stebbins, 1966, op. cit.).

THAMNOPHIS ELEGANS VAGRANS (Wandering Garter Snake). USA: ARIZONA: Mohave Co: 0.4 km NW Overnight Pond; T34N, R12W, NW Sec. 18, 1820 m. 16 June 1983. T. R. Soderquist. LACM 136190. Extends range 140 km W of North Rim, Arizona (Fowlie, J. A. 1965. The Snakes of Arizona. Azul Quinta Press, Fallbrook, CA). One additional specimen collected in Mohave Co. at Crosby Tank, 10 km NW of Mt. Trumbull; T35N, R9W, NW Sec. 27, 1820 m. 21 August 1980. N. R. Middlebrook. LACM 136191.

CROTALUS MOLOSSUS MOLOSSUS (Blacktail Rattlesnake). USA: ARIZONA: Mohave Co: Trail Canyon at Parashant Canyon; T33N, R10W, NE Sec. 11, 1210 m. 19 May 1979. J. Morgart and W. Stager. LACM 136193. Extends range 67 km NW (across Colorado River) from Havasupi (Havasu) Canyon, Coconino Co. (Fowlie, 1965, op. cit.). According to the late John Riffy, National Park Service Ranger, *C.m. molossus* is commonly seen in Tuweep Valley, 21 km E of Parashant Canyon (pers. comm. to NRM).

BOOK REVIEWS

Mississippi Herpetology, by Ren Lohoefener and Ronald Altig. 1983. Mississippi State University Research Center Bulletin 1. 66 pp. $5.00.

An informative and inexpensive book on the amphibians and reptiles native to the state of Mississippi. The page size is 8½ x 11 inches. Three state maps in the foreword section of the book provide the following: county outline and county name (numbered with separate list of names), and locations of physiographic provinces; the name and location of major river systems (watersheds) plus the Gulf of Mexico; and the forest types of Mississippi. There are also eight small outline maps of Mississippi showing "approximate boundaries of eight herpetofauna groupings in Mississippi."

Major page space is devoted to keys to species and subspecies (9 pages) and an extensive bibliography which is presented in two forms: Guide to Literature Cited (4 pages) and Bibliography (11 pages). The guide to literature cited is a listing of references by species which are in alphabetical order. I personally have not seen this reference listing used in a regional herpetological publication. A valuable section entitled "Notes" contains helpful information on how the authors resolved problems of taxonomy and species distribution while updating the checklist. The checklist of species and subspecies is not in phylogenetic order. It begins with toads and frogs (Anura) and ends with turtles and tortoises (Testudinata). The common and scientific names are the same used by Collins, et al., 1982, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles* (SSAR). The authors' names for species and subspecies were omitted from the checklist.

The dichotomous keys are generally easily read, are well constructed and should be useful in college herpetology classes. I found the arrangements of keys confusing. The keys are not in phylogenetic order. The first key covers crocodilians, followed by adult toads and frogs, then larval salamanders, then toad and frog tadpoles, then adult salamanders, etc. It would seem both logical and helpful to have placed the keys in phylogenetic order, including the placement of amphibian larvae keys before the adult (metamorphosed) sections.

The last table in the book lists the rare, threatened and endangered amphibians and reptiles of Mississippi. This is an important list and should be useful in herpetology classes as well as wildlife conservation agencies and organizations.

The last section is labeled "Appendix" but could also be titled "Illustrated Glossary." A total of 57 terms are defined and many are illustrated with outline drawings of amphibians and reptiles.

Apart from the cover drawing of a yellow-blotched sawback *(Graptemys flavimaculata)* by the senior author and the line drawings in the Appendix, there are no other illustrations or photographs. Black and white photographs of the various physiographic provinces or the state's rare and endangered species of amphibians and reptiles would have added substantially to the book.

This is a much needed reference and one that should be useful in college biology and herpetology classes within the state of Mississippi.

The Book of Indian Reptiles, by J. C. Daniel. Bombay Natural History Society (Hornbill House, Shahid Bhagat Singh Road, BOMBAY 400023, INDIA) 141 pp. 1983. $7.50 plus $3.00 mailing fee.

This is the latest contribution to a growing Indian natural history series sponsored by the Bombay Natural History Society (BNHS). The author, Dr. J. C. Daniel, is the current curator of the society and one of India's best known naturalists.

General information on reptiles is provided in a short introduction and for each order at the beginning of each major section — Crocodiles, Turtles and Tortoises, Lizards and Snakes. The majority of the text is concerned with the natural history of the common species inhabiting the Indian subcontinent. Brief accounts are also provided for some of the rare and seldom seen forms. Subjects covered in the major accounts include local names,

size, identification, coloration, distribution and habitat, habits, food, breeding, and conservation status. Folklore, derivation of names and a variety of other information are included sporadically. For each subject the author interweaves cited literature accounts along with his own observations. Three species of crocodiles, 28 turtles, 45 lizards and 49 snakes are covered in the text.

Accompanying the text are 41 colored and 13 monochrome plates as well as numerous line drawings reprinted from the reptile volumes of **The Fauna of British India** by Malcolm Smith. The plates accompanying the crocodile, turtle and lizard sections are mostly photographs varying from fair to excellent quality. The plates of snakes consist chiefly of the attractive drawings that accompanied the series on common Indian snakes by Col. Frank Wall that graced the pages of the BNHS Journal early in the century. These have generally reproduced well but (e.g. the blind snakes p. 59) details of the scalation are vague in a few.

My criticisms are few and minor. I believe taxonomic keys would increase the utility of the book. Some identification of species is possible through use of the plates and the brief sections of diagnostic features. However, lack of keys and of comprehensive coverage greatly limits this function. In future editions, plate numbers should be included with the text. As the plates are often not particularly close to the corresponding text, one must consult the Table of Contents to see if there is an accompanying plate. I caught several typographical errors and at least one line omission (page 57) but these are too few to detract.

One serious error in content is found on page 25. Here the relatively dull colored male of *Kachuga dhongoka* is described as having: "red longitudinal stripes on the neck, red or yellow spots on the throat, head red above with blue sides." This coloration is actually characteristic of male *Kachuga kachuga*.

The underlying philosophy of the BNHS natural history series has been to expand public awareness of the Indian fauna as a necessary prerequisite for conservation action. Being concise and easily readable, **The Book of Indian Reptiles** should serve this purpose well. Besides giving the layman a quick overview to the Indian species, it provides the scientist with updated nomenclature and natural history references which augment the standard but now dated reference, **The Fauna of British India** series.

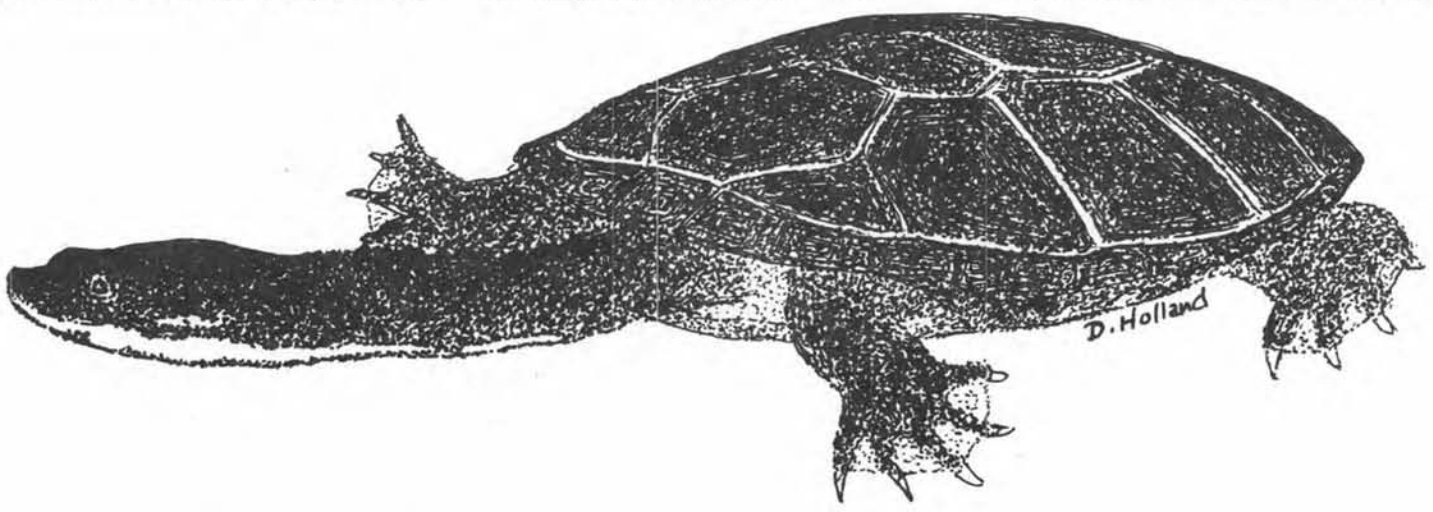
The Endangered Species Handbook, by Greta Nilsson. 1983. The Animal Welfare Institute, P.O. Box 3650 Washington, D.C. 20007, U.S.A. 249 pp. $5.00.

Endangered species are those on their way to extinction. In a sense, extinction is inevitable; most species have a limited "life span" although their "lives" may be millions of years long. Such extinctions occur naturally as the environment changes or artificially as a result of man's activities. Unfortunately, man has caused an alarming increase in the rate of extinctions. It has been estimated that between 1600 and 1973 the rate of extinctions of birds and mammals was between 5 and 50 times greater than it was through most of the evolutionary past. **The Endangered Species Handbook** documents the human activities that diminish the duration of existence for many species.



Driving a species to extinction by overhunting or habitat destruction is the ultimate insult. Some individuals, including Christine Stevens, President of the Animal Welfare Institute and author of the Foreword to this book, argue for the sanctity of life, and against the injustice and irreverence inherent in the destruction of a species. Others, such as Under Secretary of State James L. Buckley in the Opening Remarks, make the anthropocentric argument that high rates of extinctions reduce the potential growth of biological knowledge that might be used to improve health and nutrition. Inherent in the "Projects" section of the book is the view that living things should be preserved for their beauty and remarkable complexity. What arguments change the minds of individuals holding guns or operating bulldozers?

In its content and organization, **The Endangered Species Handbook** argues for the legislative process. It is primarily through the actions of individuals who eventually and collectively influence laws that environments are safeguarded and destructive habits ameliorated. The book attempts to educate individuals who can effect change and to provide ammunition for those who are gunning for anti-conservationists. It offers sobering statistics on the hunting of whales, the devouring of sea turtles, and the trampling of wildflowers. It documents a multitude of human activities responsible for the decline in animal populations.

This book is a treasure chest, full of all manner of jewels. It is divided into three major sections. The first section, "Vanishing Wildlife," gives an overview of why and how some species have been driven to extinction. Of interest to herpetologists are sections documenting reptile extinctions and the devastating effect the reptile trade in meats and skins has had on natural populations. How pet collectors have threatened particular reptile species is also sobering. That amphibians are some of the first victims of acid rain is well documented in another essay and should drive all readers to immediate environmental action.

The second major section of the book documents legislation at international, national, state, and local levels. An inspirational portion of this section is a group of essays entitled "People Who Make a Difference," which describes the achievements of individuals who have helped circumvent extinction for particular species. This section also suggests projects that will increase student awareness of animal behavior, ecology, and conservation. This latter portion, certain to be of interest to biology teachers, varies in its usefulness. No age level is suggested for the projects, which range from grade school to college. Some projects seem more in the realm of animal "awareness" than animal conservation while others test specific hypotheses. Herpetologists will want to read some of the special essays, particularly "Endangered Reptiles and Amphibians" by Dr. George Middendorf and "Evaluate Your Local Zoo" by Peter Batten.

The final section of the book, entitled "Resources," provides annotated film and

book lists, names and addresses of conservation organizations, and a species-by-species list of extinct and endangered vertebrates.

The book has its imperfections. Plants are mentioned, but the emphasis is clearly on animals. Although the book is well referenced, the sources to which the author refers are only rarely original research. In one glaring instance Carl Sagan is cited in his volume COSMOS as an expert on whale communication. The practice of using one secondary source as a reference for another secondary source is unfortunate. However, these criticisms do not diminish the real usefulness of **The Endangered Species Handbook.**

This book provides a wealth of facts and figures—just the sort of thing that might make an impression when writing to one's senator about environmental issues. I recommend that you buy this book. Use it in battle.

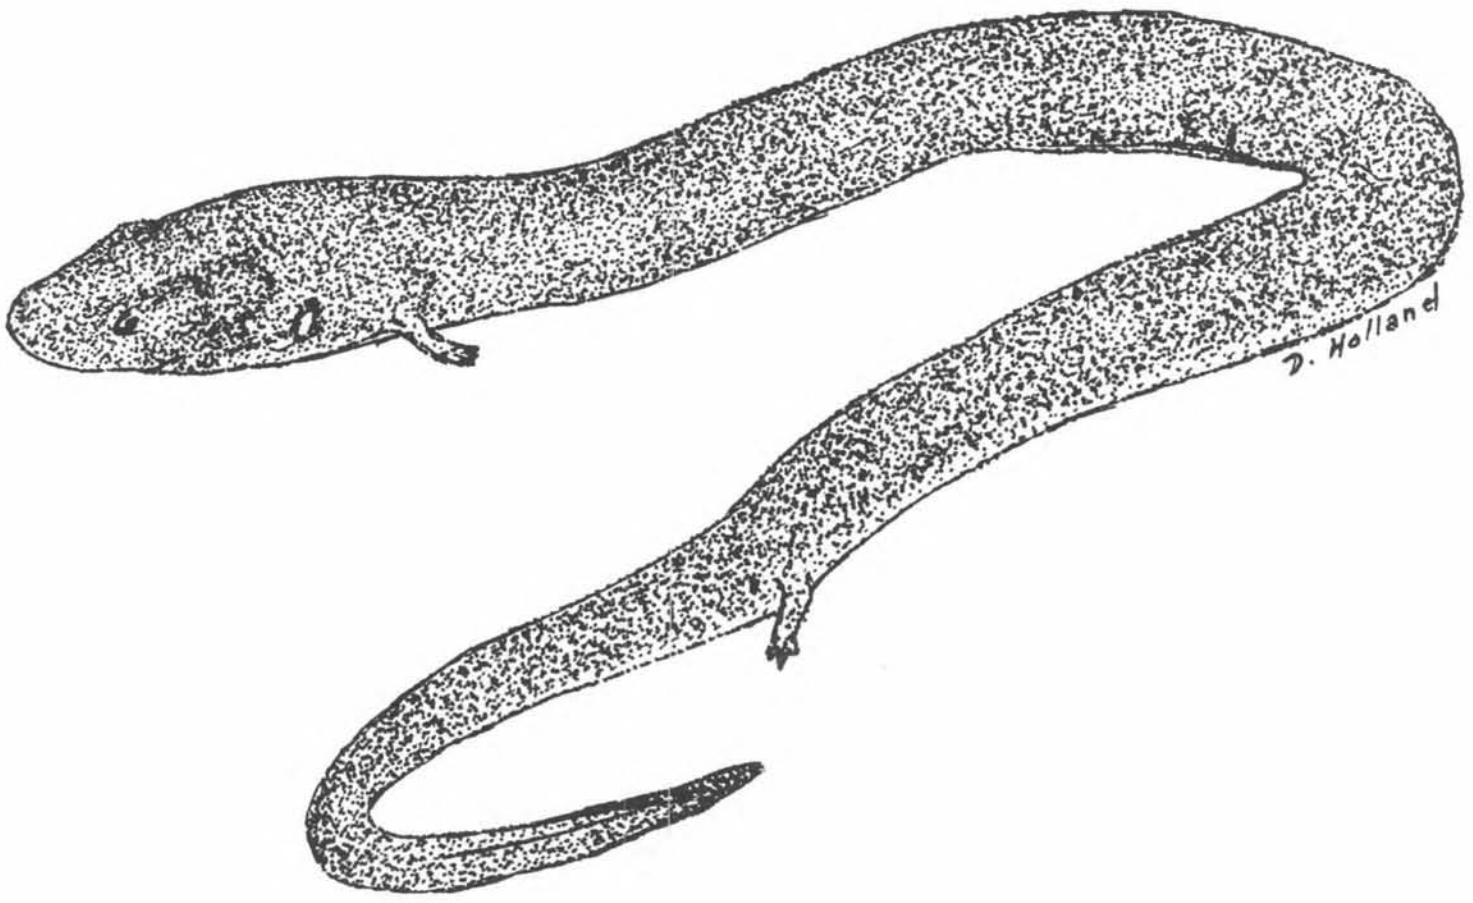
Vertebrate Ecology and Systematics. A Tribute to Henry S. Fitch, edited by Richard A. Siegel, Lawrence E. Hunt, James L. Knight, Luis Malaret and Nancy L. Zuschlag. 1984. 278 pp., ill. $30.00, paperback. Museum of Natural History, University of Kansas, Lawrence, Kansas 66045.

Collections of scientific papers honoring venerable population biologists seem to be proliferating of late. The present volume, although perhaps a trifle more modest than those dedicated to G. E. Hutchinson, R. H. MacArthur, and E. E. Williams, nonetheless stands as an equally substantial tribute to another eminent field worker, Henry S. Fitch.



Appropriately, population studies of snakes dominate this volume (Fitch not only pioneered difficult work on snake ecology, but also contributed some of the most detailed and lasting ecological studies of serpents). Snakes are exceedingly intractable subjects for population studies, being cryptic, rare and mercilessly persecuted by humans (including herpetologists).

In the introduction, Duellman exploits the turtle-hare analogy, pointing out that Fitch avoided biological fads and jargon (often glib, fast and simplistic) in preference for solid natural history, frequently painstakingly slow and tedious. Fitch's wife, Virginia, provides a complete list of his 150 publications over the past half century, which encompass a wide variety of subjects, ranging from bird behavior to reptilian ecology. Fitch's studies include work on prairie succession, spiders, frogs, salamanders, turtles, hawks, owls, other birds, armadillos, bats, coyotes, opossums, and rodents, although the vast majority of his papers are on lizards and snakes.

Some 18 chapters follow, 8 of which are on snakes, 3 on lizards, and 2 on anurans. One chapter is devoted to reptilian chemoreception, another to herpetogeography, one to systematics of the percid fish *Etheostoma lepidum*, one to a turtle population study, and another (by John, son of Fitch) to habitat selection in the deermouse, *Peromyscus maniculatus*. The final chapter describes a new species of *Anolis* lizard named *fitchi*, of course, after the only biologist to have published field observations on the species.

This Festschrift is made even more wonderful by its appearance during the lifetime of its tributee. Congratulations, Henry, on your most productive scientific career (far from over!) and on the truly magnificent impact that you have had on population ecology.

ANNOUNCING
A LIMITED TIME 25% DISCOUNT SALE FOR SELECTED SSAR PUBLICATIONS

The following publications are offered at a 25% discount (from our 1984 price sheet) for orders received prior to June 30, 1985.

Journal of Herpetology, Vols. 1-17: All volumes and numbers that are in stock (see below for out-of-print numbers). Prices reduced from $5.00 to $3.75 per individual number of each volume. Regular price = $230.00 for the 46 available individual numbers. Sale price = $172.50.

Herpetological Review, Vols. 1-14: All volumes and numbers that are in stock (see below for out-of-print numbers). Prices reduced from $2.00 to $1.50 per individual number of each volume. Regular price = $124.00 for the 62 available numbers. Sale price = $93.00.

J. of Herpetol. Nos. Out-of-Print
- Vol. 3, nos. 1-2 (1969)
- Vol. 4, nos. 1-2 (1970)
- Vol. 4, nos. 3-4 (1970)
- Vol. 5, nos. 3-4 (1971)
- Vol. 6, no. 1 (1972)
- Vol. 6, no. 2 (1972)
- Vol. 8, no. 1 (1974)
- Vol. 9, no. 1 (1975)
- Vol. 9, no. 2 (1975)
- Vol. 9, no. 4 (1975)

Herp. Review Nos. Out-of-Print
- Vol. 1, no. 7 (1969)
- Vol. 3, no. 2 (1971)
- Vol. 4, no. 1 (1972)
- Vol. 6, no. 4 (1975)

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

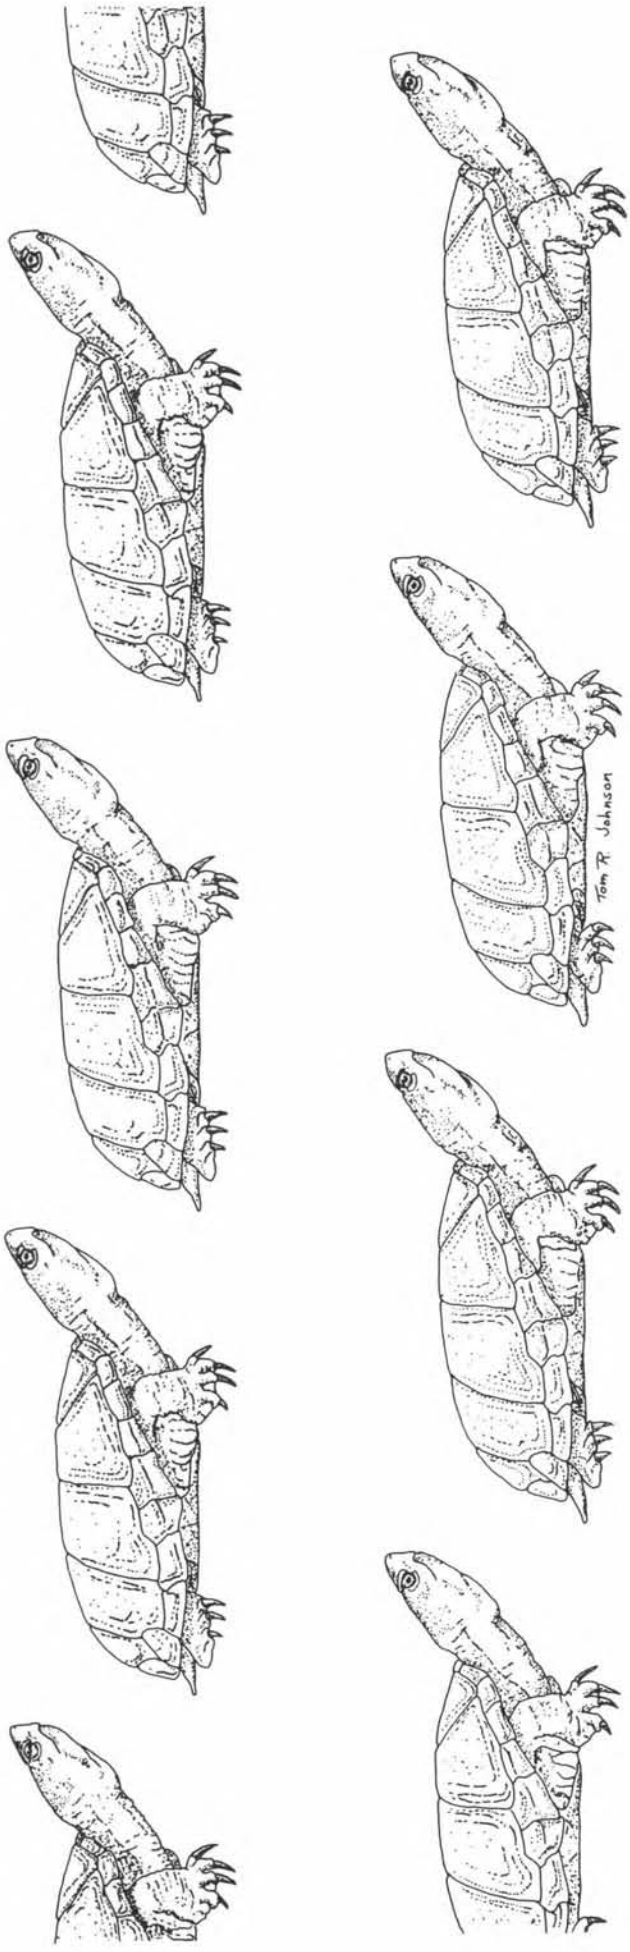
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), occasional issues of **Facsimile Reprints in Herpetology,** and **Recent Herpetological Literature.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1984

Student member	$17.00*
Regular member	$22.00*
Sustaining member	$35.00
Contributing member	$50.00
Institutional	$40.00

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).



*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

HERPETOLOGY IN AFRICA
By Bill Branch 66

FEATURES
The status of *Micrurus ruatanus* (Günther), a coral snake endemic to the Bay Islands of Honduras, by Larry David Wilson 67
Observations of the feeding habits of the short-tailed snake, *Stilosoma extenuatum* in captivity, by Henry R. Mushinsky 67
Disease studies aid Kemp's ridley sea turtle headstart research, by John C. Clary, III and Jorge K. Leong 69
The establishment of *Podarcis muralis* in Cincinatti, Ohio, by Stanley E. Hedeen 70

TECHNIQUES
A modified seining technique for single person sampling of deep or cold water, by Eric J. Routman 72
A tagging method for use in hatchling turtles, by David A. Galbraith and Ronald J. Brooks 73
Paint-marking the rattle of rattlesnakes, by William S. Brown, V.P.J. Gannon, and Diane M. Secoy 75

GEOGRAPHIC DISTRIBUTION
New records 76
New distributional records for some semiaquatic amphibians and reptiles from the Rio Sabinas Basin, Coahuila, Mexico, by Robert Powell, Nicholas A. Laposha, Donald D. Smith and John S. Parmerlee 78

BOOK REVIEWS
Amphibians and Reptiles of New England: Habitats and Natural History, by Robert J. Craig 79
A Review of the Diseases and Treatments of Captive Turtles, by David C. Zeitz 80
Iguanas of the World: Their Behavior, Ecology and Conservation, by Gary W. Ferguson 80
The Ecological Impact of Man on the South Florida Herpetofauna, by R. D. Bartlett 84

1985 ANNUAL MEETING

The 1985 annual meeting will take place at The University of South Florida in Tampa, 4-9 August.

SSAR members are reminded that the Tampa meeting will include the ever-popular Annual Auction of herpetologically related books and other items. It is not too early to start collecting your collectibles, forwarding them (or a statement of your intention to bring them) to meeting chairman:

Henry R. Mushinsky
Department of Biology
University of South Florida
Tampa, Florida 33620, U.S.A.

David Dennis and Kraig Adler, co-producers of the "Herpetologists Then and Now" slide presentation given at the Oklahoma ASIH/HL/SSAR meeting, request that society members send them duplicate slides of memorable (or forgettable) herpetological happenings — and their participants — for inclusion in future presentations. Anonymity of donors is guaranteed. Slides should be mailed to:

David M. Dennis
General Biology Section
The Ohio State University
1060 Carmack Road
Columbus, Ohio 43210, U.S.A. ●

SSAR BUSINESS

SYMPOSIUM PROPOSALS FOR 1986 SSAR MEETING

Proposals for symposia for the **1986** SSAR meeting are now being accepted. In order to allow for necessary planning and coordination of symposia, the *deadline* for receipt of proposals for the **1986** meeting is 1 JANUARY 1985. Further information may be obtained from, and proposals submitted to:

Dr. Lynne Houck
Department of Biology
University of Chicago
1103 E. 57th Street
Chicago, Illinois 60637, U.S.A. ●

1984 SSAR GRANTS-IN-HERPETOLOGY AWARDS

The Society for the Study of Amphibians and Reptiles is pleased to announce the following awards in the 1984 Grants-in-Herpetology Program:

GRADUATE STUDENT RESEARCH:

Trip Lamb, Department of Zoology, University of Georgia. "An investigation of introgressive hybridization between the barking treefrog *(Hyla gratiosa)* and the green treefrog *(Hyla cinerea)* using mitochrondrial DNA analysis." $280.

Martha K. Pancak, Department of EPO Biology, University of Colorado. "Endocrine regulation of oocyte development in the Bidder's Organ, a remnant ovary in male toads." $280.

REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS:

Joseph C. Mitchell, Department of Biology, University of Richmond. "Reptiles and amphibians of far southwestern Virginia: a biogeographical and ecological survey." $240.

Yehudah L. Werner, Department of Zoology, Hebrew University of Jerusalem. "A gecko research facility." $350.

HERPETOLOGICAL CONSERVATION:

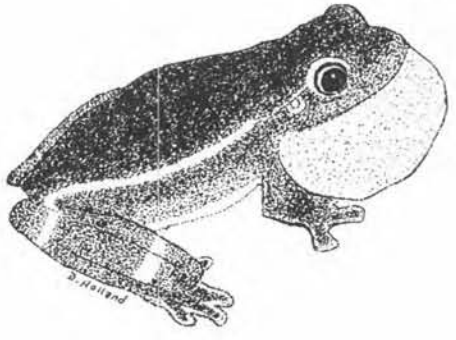
Robert E. Herrington, Department of Zoology, Washington State University. "The ecology, distribution, and habitat requirements of the Larch Mountain Salamander, *Plethodon larselli*." $430.

HERPETOLOGICAL RESEARCH IN ZOOS:

Michael K. Stoskopf, National Aquarium in Baltimore. "Amino glycoside kinetics in 3 families of Anura." $400.

FIELD WORK:

Calvin A. Porter, Department of Zoology, Brigham Young University. "Chromosomal variation in the iguanid lizard *Sceloporus grammicus* in central Mexico." $215.



Mac F. Given, Biological Sciences Group, University of Connecticut. "Social behavior and acoustic interactions of the carpenter frog, *Rana virgatipes*." $215.

The number of proposals received in each category for this year and last year is:

	1984	1983
Conservation Research	9	15
Field Work	9	—
Graduate Student Research	33	34
Regional Herp. Societies	4	5
Zoo Research	5	0
Total:	60	54

SSAR extends its congratuations to all recipients of awards and encourages the submission of proposals for next year's program. Further details on the 1985 Grants-in-Herpetology program, and the deadline for receipt of proposals, will appear in the December issue of *HR*.

SSAR expresses its thanks to the 1984 Grants-in-Herpetology Committee, composed of Linda R. Maxson (Chairperson), James P. Bacon (Herpetological Research in Zoos), Donald C. Forester (Field Work), John B. Iverson (Herpetological Conservation), Robert W. Murphy (Graduate Student Research), and Malvin L. Skaroff (Regional Herpetological Society Programs). ●

IN MEMORIAM — FEDERICO MEDEM

On May 1, 1984, Federico Medem died of cancer in Bogotá, Colombia. He is survived by his widow, Flor Angela and daughter, Dina Maria. Not only has herpetology lost one of its most dedicated scholars, but more, the world has lost a rare human being; a man unaffected by the legend that was his life.

Friedrich von Medem Medem was born August 29, 1912 in Riga, Latvia. His family was nobility and many were notables at the Imperial Russian Court. An uncle and grandfather were generals in the Russian Army. His other grandfather had been chief of diplomatic mission from the tsar to China and so outstanding were his accomplishments, that when he died there, the other legations erected a monument to honor his memory.

In 1917, the Bolshevik Revolution obliged the Medems to flee their palatial estates and young Friedrich was taken to Berlin. From 1925 to 1928, he attended gymnasia in Namslau and Liegnitz, Silesia and then returned to Riga to receive his diploma in German humanities. Between 1936 and 1940, he studied at the Humboldt University and the University of Tuebingen. He then went to the Stazione Zoologica in Naples, Italy to research his doctoral thesis. He received his doctorate in Natural Sciences from Humboldt University in 1942 and later worked as assistant to the director of the Max Planck Institute in Hechingen, Germany. In those years, a dark star was rising over Germany and Medem watched with horror the lunatic rantings of Adolph Hitler. Although he wished only to occupy himself with science and literature, he could not dissemble his loathing for the new Nazi regime and he was eventually drafted into a special batallion of political dissidents and sent to the Russian front, where he was seriously wounded. After the war, he went to the Institute of Zoology at Berne University in Switzerland as an instructor. There he met Doctor Mario Laserna, who invited him to teach at the new University de Los Andes in Bogotá, Colombia.

In June, 1950, he arrived in Colombia. This was his first time in the Americas and although he spoke Russian, German and Italian fluently, he knew practically no Spanish. His finances were equally meager and he often referred to himself as a displaced person at that point in his life. Vicissitudes such as these never deterred him, however, and in the next thirty-four years he would establish himself as the foremost naturalist in the country and one of the world's leading experts on the natural history of crocodilians. Along the way, he adopted the name Federico, acquired Colombian citizenship and married his beautiful Colombian wife.

During his early years in Colombia, Federico lived for months among indian tribes, many of whom had probably never seen any outsider. With them, he explored the forests and rivers, submersing himself totally in the study of their exciting tropical world. His methodical nature and his absolute disregard for pain and discomfort impressed them greatly. One Guahibo tribe not only adopted him, but gave him one of the specially carved

wooden stools reserved solely for caciques. Federico was similarly impressed by the indians and identified with their spiritual kinship with Nature. Among his many stories about the tribes he had lived with were those about their sense of humor. Although they are quite prudish about personal sexual matters, they delight in the coarsest jokes and insults directed at one another and sometimes at the strange white man who was in their midst. Count von Medem, descended of a long line of nobility, was as unaffected by their stinging wit as he was by the vicious bites of the huge tabanids whose primary hosts were crocodiles and caimans. A species of this fly was named *medemi,* which not only honors him as its discoverer, but also commemorates his legendary indifference to the bite. The list of new species and subspecies named after him spans the orders of the animal kingdom, most named to honor Federico as discoverer.

Between 1953 and 1961, Medem received two separate grants from the Guggenheim Foundation to travel in the United States, to meet with colleagues and to study specimens preserved in museums and universities. In later years, he would sponsor other young scientists for similar grants. Then, for the next five years, he directed the Faunistic Section of the Corporación Autonoma Regional de los Valles del Magdalena y Sinu at Cartagena. It was there that he met and married Flor Angela Cortés.

In 1966, Federico was named director of the 'Roberto Franco' Institute in Villavicencio, which had been the site of the famous malaria research by Marston Bates and others in the 1940s. Villavicencio, at the foot of the Andes, is the gateway to the great Colombian savannahs and the rain forests to the south. Federico never enjoyed the higher altitudes and this new environment suited him perfectly. A year later, the National University appointed him full professor in a non-teaching capacity that he might devote all his time to his research. His more than ninety publications, including two books, attest to his tireless work.

In 1972-73, he traveled throughout South America gathering scientific data and studying the growing commerce in reptile hides. The trip was sponsored by the New York Zoological Society. He worked constantly to inform the world of the serious depredations upon wildlife species, especially the crocodilians. He was a born conservationist; a conservationist long before it became the thing to be. In the years to come, he would atttend international conservation congresses in Australia, New Guinea, Switzerland, India, Costa Rica and the U.S. In 1981, he was retained by FAO to go to Botswana and evaluate a management and conservation project for Nile crocodiles. For the last several years of his life, he was vice-chairman of the IUCN/SSC for all of South America. In September, 1983, the National University awarded him its highest possible academic tribute, the Medalla Al Merito Universitario. At that time, he was working on the manuscript of his third book, The Turtles of Colombia, which he was never to see completed.

For almost two decades, Fred Medem's home in Villavicencio was a mecca for colleagues, students and friends from all parts of the world. His courtly charm was denied to none and the only credentials needed was a sincere desire for knowledge. He was impatient with any sort of affectation or pretentiousness. He had none himself.

I first met Fred in February, 1979, while I was working to develop a zoo near Bogotá. In 1980, he invited me to live at the Institute and work for him as his personal secretary and librarian. I accepted this honor with alacrity and in the next year and a half, I came to know this unique and unforgettable man. After I left Colombia, we corresponded actively until shortly before his death.

MIKE WILLIAMSON
Curator - Dallas Zoo
Dallas, Texas 75203-2996, U.S.A. ●

LEGISLATIVE ALERT

COMMENTS SOUGHT ON *Sternotherus m. depressus*

The U. S. Fish and Wildlife Service announced a positive finding on a petition by the Environmental Defense Fund to list the flattened musk turtle, *Sternotherus minor depressus* (or *S. depressus*) as a threatened species (F.R. 49:67:13558-59, Apr. 5, 84). The petition was received by the Service on December 1, 1983, and a decision must be reached within 12 months of that date as to whether the requested action is warranted.

The Service is now receiving comments and soliciting data concerning the turtle; it is especially interested in information regarding "taxonomy, distribution, any recommended critical habitat for the species, and threats."

Comments and information may be submitted "until further notice" to the Associate Director — Federal Assistance, U. S. Fish and Wildlife Service, Department of the Interior, Washington, D.C. 20240. Additional information may be obtained by contacting John L. Spinks, Jr., Chief, Office of Endangered Species, same address as above. ●

FEDERAL REGISTER NOTICES

The SSAR Conservation Committee monitors the Federal Register and excerpts items concerning the herpetological resource. The following summaries briefly highlight those issues and identify the volume and date of publication. Those individuals interested in more detail are referred to the appropriate issue of the Register.

Volume 48, No. 161, pp. 37494-37498. August 18, 1983. 50 CFR Part 23. Proposed findings and rule for Export of . . . **American Alligator** . . . Taken in 1983-84 and Subsequent Seasons. Deadline for comments was September 19, 1983.

The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) regulates international trade in certain animal and plant species. This proposed rule identifies the conditions for export for legally taken American alligator *(Alligator mississippiensis)* hides taken in Florida and Louisiana for the 1983-85 harvests.

Volume 48, No. 226, pp. 52740-52743. November 22, 1983. 50 CFR Part 17. Final Rule to Remove the Florida Population of the **Pine Barrens Treefrog** from the List of Endangered and Threatened Wildlife and To Rescind Previously Determined Critical Habitat. The rule became effective on December 22, 1983.

A final rule published on November 11, 1977 (42 FR 58754-58756) determined that the Florida population of the Pine Barrens treefrog *(Hyla andersonii)* was endangered. A critical habitat designation became effective on December 8, 1977. Subsequent investigations by the Florida Game and Fresh Water Fish Commission conducted pursuant to an Endangered Species Cooperative Agreement identified many additional sites occupied by this species. A proposed rule was published on September 15, 1982 (47 FR 40673-40676); six responses were received; five favored delisting and one opposed. This final rule officially removes the Florida population of *H. andersonii* from the federal endangered species list.

Volume 49, No. 5, pp. 1058-1060. January 9, 1984. 50 CFR Part 23. Final Findings and Rule for Export of **American Alligators** Taken in 1983-85 Harvest Seasons. The findings became effective on January 9, 1984.

The rule states the final conditions under which American alligator *(Alligator mississippiensis)* hides may be exported from Florida and Louisiana. Hides from animals taken on or before December 31, 1985 must be clearly identified as to species, state of origin and season of taking and must be tagged by a permanently attached, serially numbered tag of a type approved by the Service that is attached under conditions established by the Service. A summary of this rule is also available in the Endangered Species Bulletin (Volume IX, No. 3, March, 1984).

Volume 49, No. 11, pp. 1992-1994. January 17, 1984. 50 CFR Part 17. Final rule: Determination That the **Wyoming Toad** *(Bufo hemiophrys baxteri)* Is an Endangered Species. The rule became effective on February 16, 1984.

The Wyoming toad was discovered in 1946. It is closely related to the Canadian toad *(Bufo h. hemiophrys)* but was identified as a distinct subspecies in 1968. It is believed to be a glacial relict and occurs only in a restricted area in Wyoming. Surveys in recent years have yielded but few animals. A proposed rule was published on January 27, 1983 (48 FR 3794); five comments were received, all supportive of listing the Wyoming toad as an endangered species. No critical habitat designations have been made to date.

Volume 49, No. 12, p. 2128. January 18, 1984. 50 CFR Part 23. Notice of Amendment to Appendix and Request for Comments on: Indian Snakes Added to Appendix III of

Endangered Species Convention. Deadline for comments was February 3, 1984.

The following species were submitted by the Government of the Republic of India for inclusion in Appendix III of CITES:

Family Colubridae:
Atretium schistosum (olive keelback water snake)
Cerberus rhynchops (dog-faced water snake)
Natrix piscator (checkered keelback water snake)
Pytas mucosus (Indian rat snake)

Family Elapidae:
Naja naja (Indian cobra)
Ophiophagus hannah (king cobra)

Family Viperidae:
Vipera russellii (Russell's viper)

Volume 49, No. 41, pp. 7394-7398. February 29, 1984. 50 CFR Part 17. Final rule: Listing of Two Spanish Reptiles and the Delisting of the Indian Flap-Shelled Turtle. The rule became effective on March 30, 1984.

The **Hierro giant lizard** *(Gallotia simonyi simonyi)* is determined to be endangered. It is a large herbivorous species known only in the Canary Islands. It was believed extinct until 1975, but survives on a steep rocky arid cliff. Half of the estimated 200 individuals in 1975 were juveniles. Possible threats include proposed development, competition with goats, over-collecting and gull predation on juveniles. No critical habitat has been designated.

The **Ibiza wall lizard** *(Podarcis pityusensis)* is determined to be threatened. It is found on the Balearic Islands in the Mediterranean Sea. Threats and impacts include gull predation, scientific and commercial collecting, human-mediated hybridization of the subspecies, habitat alteration and destruction, and poisoning. No critical habitat has been designated.

The **Indian flap-shelled turtle** *(Lissemys punctata punctata)* has been removed from the endangered species list. It was listed on June 14, 1976 (41 FR 24062-24067) based on recommendations from Bangladesh that it be listed on CITES Appendix I. Subsequent investigations indicate that it is one of the most common turtles in India and there is no justification for retaining it on the endangered species list. Although provisions of the Endangered Species Act do not apply after the effective date of the rule, the species still remains on the CITES Appendix I and therefore is subject to trade restrictions.

A summary of this rule may also be found in the Endangered Species Bulletin (Volume IX, No. 3, March 1984).

Volume 49, No. 41, pp. 7416-7417. February 29, 1984. 50 CFR Part 17. Notice of: Findings on a Petition to List the **Alligator Snapping Turtle** as a Threatened Species. The Findings was made on February 10, 1984.

The Service received a petition on February 23, 1983, from Dr. Peter C. H. Pritchard, to list the alligator snapping turtle *(Malaclemys temmincki)*. The species was included in the Review of Vertebrate Wildlife for Listing as Endangered or Threatened Species published in the Register on December 30, 1982. The species appears to have declined throughout most of its range, although local populations in some areas appear stable. There was both support for and opposition to listing at this time. The Service concluded by stating there are insufficient data at this time to support listing but that it will continue to monitor the status of the turtle. An additional summary of this finding may be found in the Endangered Species Bulletin (Volume IX, No. 3, March 1984).

SOCIETIES

OREGON HERPETOLOGICAL SOCIETY REVIVED

The Oregon Herpetological Society, which originated in 1955, has recently emerged from a decade of dormancy and finds itself alive and ready for action. A newsletter was published in June 1984 and a field trip was held in the same month. Regular meetings are held on the second Sunday of each month (except July and August), beginning at 7:00 P.M., in Eugene. Membership is $5 (regular) or $4 (corresponding) annually. For further information contact:

Mr. David Olson
OHS Treasurer
981 West 8th Avenue, #10
Eugene, Oregon 97402, U.S.A. ●

MINNESOTA HERP SOCIETY RECEIVES GRANT

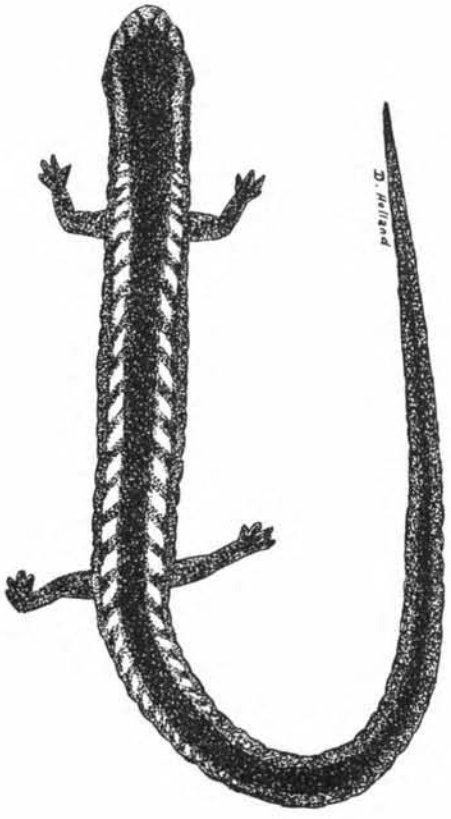
The Minnesota Herpetological Society has received a grant from the Minnesota Department of Natural Resources to do field work in the Missouri River Drainage in the southwestern corner of the state. The $1500 grant is to support three field trips to the area. ●

AMPHIBIA-REPTILIA AND THE "SOCIETAS EUROPAEA HERPETOLOGICA"

In 1980, *Amphibia-Reptilia*—a major new international journal of herpetology—was established in Europe, yet many of our colleagues, especially those in America, are unaware of it and fewer still have seen copies. We take an opportunity, then, to review this journal, now completing its fourth volume in 1984, to discuss its importance for world herpetology and a potential problem for its further development.

In subject matter and geographical coverage *Amphibia-Reptilia* is quite cosmopolitan. To illustrate the diversity of coverage, the articles in volume 3 (1982) can be divided into the following categories: seven on molecular and karyotypic studies; five on ecology and behavior; five on taxonomy and systematics; three on anatomy; three distributional and faunistic papers; three on reproduction; two on development; and one other paper each on genetics, evolution, physiology, conservation and paleontology. The journal emphasizes European species (23 of the 33 papers in volume 3), but nearly one-third of the articles covered species from other regions including three on Asia; three on the Americas; one each for Africa and Australia; and with two others that are world-wide in coverage. However, whatever the geographic focus, the subject matter of most articles is of general interest. There is also a section for book reviews and newsnotes at the end of each issue. The vast majority of papers is in English (in volume 3, 25 papers) but also French (5), Spanish (2) and German (1)—the four official languages of the journal. English abstracts are provided for all papers.

The journal is quarterly, although double numbers occasionally appear. The format and typography are highly professional and the photographs are of an especially high standard. To date, each volume comprises about 400 pages. In general, the quality of the articles and of the editing is very good.



One cannot fairly review *Amphibia-Reptilia* without commenting on its sponsoring society. The "Societas Europaea Herpetologica" (SEH) is the first multi-national rather than linguistic or national society to develop in Europe. Two pivotal meetings provided the real impetus for a pan-European society, both for a society and the journal. Following discussions between French and German herpetologists, a working session was held at Montpellier, 21-23 June 1979, and the formal founding session at Bonn, 10-11 September 1979. Membership, especially among professional herpetologists in Europe, grew rapidly for several years and is now about 385 (as of March 1984). Besides the journal, biennial meetings have been held (Vienna 1981; León 1983; 1985 planned for Prague, jointly with herpetologists from Eastern Europe and the USSR) and several committees established, the most active of which is that concerning conservation.

SEH founded *Amphibia-Reptilia* in a manner quite unlike that of the comparable journals based in America. In the latter societies, for better or worse, the size and format of their respective journals developed over many years in parallel to the growing financial capabilities of the sponsoring societies. For *Amphibia-Reptilia*, on the contrary, it was decided to establish a fully professional journal at the very beginning, but in order to do so the SEH had to ask a commercial firm to publish the journal, with the society guaranteeing a certain financial support. Unfortunately, their first publisher went bankrupt during 1983 but SEH has recently contracted with the well-known firm of E. J. Brill in Leiden, to publish *Amphibia-Reptilia*. All commitments to subscribers will be honored and the journal should be back on schedule by the end of

1984. We believe that *Amphibia-Reptilia* is an excellent journal and deserves a broader readership. Compared to other journals now printed in Europe it is very modestly priced. On the other hand we note that *Amphibia-Reptilia* currently addresses itself to university and museum personnel although herpetology as a discipline is much more extensive. One would hope that the editors, in further developing their journal, will broaden the journal's appeal so that *Amphibia-Reptilia* will show up in more libraries and on more desks and, as a result, enlarge the financial base for the journal which seems necessary for its survival.

We hope that our colleagues will consider membership in SEH (which includes subscription to *Amphibia-Reptilia*), at least for a trial year. Dues for individuals are presently 75 Deutschmarks and can be paid by check, in marks, to the treasurer, Dr. Heinz Wermuth, Staatliches Museum für Naturkunde, Arsenalplatz 3, D-7140 Ludwigsburg, Federal Republic of Germany. In addition, by a special new arrangement, dues can also be paid in USA dollars, by sending a check for $32 to Dr. Wermuth.

NOW PUBLISHED!

THE TURTLES OF VENEZUELA

by Peter C. H. Pritchard and Pedro Trebbau

This book is the first in-depth treatment of a major South American turtle fauna. It covers all turtles known from Venezuela including the matamata and other sidenecks (11 species), tortoises (2 species), pond and land turtles (5 species and subspecies), and the sea turtles (5 species), together comprising half of the turtle species described from the South American continent. There is an extensive discussion of the distribution and zoogeography of South American turtles and a key to species (in both English and Spanish). Each species account consists of a synonymy followed by a diagnosis; a detailed description (including shell, soft parts, color, and sexual dimorphism); and sections on size and growth, distribution, geographic variation, habitat, feeding, reproduction, economic importance, and vernacular names. The family accounts give a detailed review of the fossil history and present distribution of all genera, worldwide, but with emphasis on South America. There is also a comprehensive bibliography and a list of locality records from throughout the entire continent for all Venezuelan taxa.

The book is beautifully illustrated. There are 48 full-page plates in color, 26 of which are original watercolors and the remainder a collection of 165 photographs of both turtles and their habitats. In addition, there are two distribution maps for each species: a spot map showing the detailed Venezuelan distribution and another map showing the continent-wide range.

The book is 414 pages, 8½ x 11 inches (21.5 x 28 cm), bound in buckram, price US $45. A special leatherbound patron's edition, in two volumes, is US $300. A four-page ad with sample color plates was published in the December 1982 issue of *Herpetological Review*, and copies may be obtained on request from Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA.

Orders may be placed with Dr. Taylor. Please make checks payable to "SSAR." All USA orders are postpaid; shipments outside the USA will be charged only the *additional* shipping costs in excess of domestic rates. Overseas customers must pay in USA funds or by International Money Order, or may charge to MasterCard or VISA (give account number and expiration date). A complete list of Society publications and membership information can be obtained from Dr. Taylor. The Society publishes *Journal of Herpetology, Facsimile Reprints in Herpetology, Herpetological Review, Herpetological Circulars, Catalogue of American Amphibians and Reptiles, Contributions to Herpetology,* and *Recent Herpetological Literature.*

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

HERPETOLOGY IN AFRICA

Africa is large, and herpetologists few. Problems of distance, finance, and, not the least, politics all limit contact between us. In my capacity as Editor/Secretary of the Herpetological Association of Africa (HAA), I have been asked to attempt an 'overview' of herpetological research on the continent. Frankly my efforts are doomed. I apologise at the outset for the parochial nature of this report; it is heavily biased towards southern Africa. Not through choice, I hasten to add. It is simply where I live and work, and the area with which I am most familiar. I appeal to all herpetologists working on African reptiles and amphibians to keep me informed of their current research projects, publications and conference announcements. Through these columns I offer them an opportunity to contact, advise and inform their colleagues.

FORTHCOMING CONFERENCES

From 16-18 July 1985, the Zoological Society of Southern Africa (ZSSA) and Herpetological Association of Africa will be holding a herpetological conference, in conjunction with the ZSSA conference on "Competition and Co-existence," at the University of Natal, Pietermaritzburg. Herpetologists interested in presenting papers are invited to contact the author for further details.

Sixth Symposium on African Amphibians, Department of Biology, University of Miami, U.S.A. 13 April 1987. Organized by the African Amphibian working group, participation in the symposium will be by invitation to scientists active in the study of African amphibians. Information can be obtained from Prof. Jay M. Savage, Department of Biology, University of Miami, Coral Gables, Florida 33124, U.S.A.

PUBLICATIONS

Herpetology of Africa. A checklist and bibiography of the Orders Amphisbaenia, Sauia and Serpentes by Kenneth R. G. Welch, 1982, 293 pp, $19.50, Robert E. Krieger Publ., Malabar, Florida. This recent publication, despite its name, is restricted to African squamates, but is nonetheless a very useful checklist. Detailed, constructive reviews by Broadley and Branch appeared in J. Herpetol. Assoc. Afr., 29:22-36, 1983. A companion volume on African amphibians is in preparation.

The Transvaal Branch of the Wildlife Society of Southern Africa has printed a large colour poster illustrating all Transvaal snakes. Copies can be obtained from the Society (P.O. Box 44344, Linden, 2104, South Africa) for R3.50.

FitzSimons' *Snakes of Southern Africa*, Delta Books, Johannesburg, 376 pp, 83 maps, 209 figs., 84 col. pls., R59.65. FitzSimons' 1962 monograph has been completely revised by Dr. D. G. Broadley, and is now the definitive treatment of the subcontinent's snakes.

Die Slange van Suidwes-Afrika by P. J. and P. J. C. Buys. Gamsberg Publ., Windhoek, R7.75 (in Afrikaans).

Danie Immelman and Pietro de Lange (University of Stellenbosch) have completed M.Sc. theses on "The cranial morphology of *Phrynomerus annectans* Werner, with special reference to the systematic position of the Phrynomerinae (Microhylidae)" and "Kidney morphology in *Geochelone pardalis*," respectively.

Niel Jacobsen (Transvaal Nature Conservation Division) has completed his M.Sc. thesis (University of Pretoria) on "The ecology of the reptiles and amphibians in the *Burkea africana - Eragrostris pallens* savanna of the Nylsvley Nature Reserve" and is now completing his survey of the Province's herpetofauna.

CURRENT RESEARCH

Dr. Mike Picker (University of Cape Town) is investigating habitat selection in *Xenopus gilli* and *X. laevis*, and hybridization between the two species. *Xenopus gilli* is an endangered amphibian and Dr. Picker is a member of the Council for Cape Platanna Conservation.

'Amphibia Zambesiaca,' a study of the amphibians of Mozambique, Malawi, Zambia, Botswana, Zimbabwe, and the Caprivi Strip of Namibia, is co-authored by D. G. Broadley and J. C. Poynton. Part 1 (Scolecomorphidae, Pipidae, Hemisidae and Arthroleptidae) has recently been published (Ann. Natal Mus., 26, 1984), and Part 2 (Ranidae) is in press. Dr. Broadley is currently working on the companion monograph - 'Reptilia Zambesiaca.'

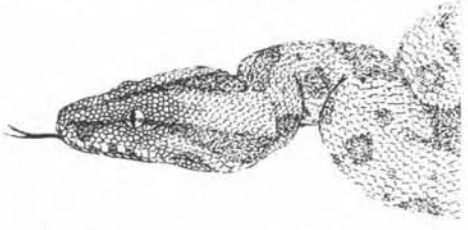
Professor Robert Capranica (Cornell University) recently completed a 4 month sabbatical, working in collaboration with Dr. Neville Passmore (University of the Witwatersrand) on mate recognition in *Kassina* and phonotaxis in *Hyperolius marmoratus*.

Jim Campbell (ex Portland State University, Oregon) has joined the Desert Ecological Research Unit in the Namib Desert to investigate body temperature regulation and digestive efficiency in *Angolosaurus skoogi* and *Aporosaura anchietae*. Physiological parameters of this investigation will be studied by Professor D. M. Mitchell, Medical School, University of the Witwatersrand.

Dr. C. W. D. Gibson (Animal Ecology Research Group, Oxford University) is continuing studies on the Aldabran giant tortoise *(Geochelone gigantea)*. Dr. Malcolm Coe, of the same department, is undertaking a survey of the Kora National Reserve, Kenya, and herpetological studies include:

1. Producing an inventory of the herpetofauna
2. Studying the activity and biomass of lizards
3. Factors affecting the breeding and dry season activity of amphibians
4. Studying the distribution and activity of the pancake tortoise *(Malocochersus tornieri)* on rock outcrops

Dr. Jim Hebrard (Department of Zoology, University of Nairobi) is studying the ecology and distribution of chamaeleons in Kenya.



NEWS

Wulf Haacke, Curator of Lower Vertebrates, Transvaal Museum, Pretoria, has won the recent Wildlife Society of Southern Africa/ Agfa Photographic competition (with a shot of an elephant!). His prize - a trip for 2 to the Galapagos!

RECENT AFRICAN HERPETOLOGICAL LITERATURE

This bibliography is published in the *Journal of the Herpetological Association of Africa*. The world literature is scanned for relevant publications. The Editor (Port Elizabeth Museum, P.O. Box 13147, Humewood 6013, South Africa) invites authors working on African Herpetology to inform him of their publications for inclusion in the bibliography.

NATURE PRINTS

BY DAVID M. DENNIS

We are pleased to offer four exquisite, full-color art prints by David M. Dennis, naturalist and professional scientific illustrator renown for his watercolors of unusual wildlife.

Plate 1: *Green Frog and Damselfly*
Plate 2: *Painted Turtle and Dragonfly*
Plate 3: *Spotted Salamanders in Courtship*
Plate 4: *Red Salamander and Hercules Beetle*

Prints measure 20 x 24 inches (51 x 61 cm), each signed and numbered by Mr. Dennis in editions limited to only 500 copies. $30 each or $95 for set of four prints plus shipping ($4.50) and any New York taxes.

Send orders to BIOGRAPHICS, 12 Eagles Head Road, Ithaca, NY 14850. Color brochure published in *Herpetological Review* (March 1983 issue) and *Wildlife Publications Review* (June 1983 issue), or available on request from BIOGRAPHICS.

THE STATUS OF *Micrurus ruatanus* (GÜNTHER), A CORAL SNAKE ENDEMIC TO THE BAY ISLANDS OF HONDURAS

Roze (1982) recently provided a systematic and biological summary of the members of the genus *Micrurus*. In this work, Roze modified the status of a number of taxa within the genus. One of these changes involved placing the nominal species *Micrurus ruatanus* (Günther), 1895, as a subspecies within *M. nigrocinctus*, a widespread Middle American species, occurring also in adjacent Colombia. The reasoning given for this shift was as follows: "Whereas no intergradation is known (Wilson and Meyer, 1972), apparently, this subspecies is related to *M. nigrocinctus*. Some specimens of *M. n. divaricatus* from Honduras (*sic*) mainland approach the high number of black bands found in the population of Isla Roatan (*sic*)." He went on to say "is *ruatanus* already a species or not (*sic*) is an open question due to its insular distribution."

Micrurus ruatanus has been discussed several times by my coworkers and myself (Wilson and Meyer, 1972; Wilson and Hahn, 1973; Wilson and Meyer, 1982). These authors considered this coral snake to be a distinct species. I would like to reaffirm this earlier position and provide the justification below.

Roze (1982) credited Wilson and Meyer (1972) with pointing out that "no intergradation is known" between *ruatanus* and the mainland members of the *nigrocinctus* complex. These authors made no such statement, inasmuch as it is obvious that an insular form is not going to intergrade with a mainland taxon. He further stated that "apparently, this subspecies *ruatanus* is related to *M. nigrocinctus*" but provided no justification for the statement, except to note the approach in "some specimens of *M. n. divaricatus* from the Honduran mainland" in high black band count to that of *M. ruatanus*.

Wilson and Meyer (1972) pointed out that Roze, in an earlier paper (1967), had misidentified a specimen of *M. nigrocinctus* from the department of Atlántida in northern Honduras as *M. ruatanus*. In spite of the statement by Wilson and Meyer (1972) that the resemblance between the mainland specimen (TCWC 21181) and insular *ruatanus* in black body band count "is only superficial," Roze (1982), apparently, used the same specimen to support his statement that "some" specimens of mainland *nigrocinctus* have black body band counts that "approach"the high numbers seen in *ruatanus*.

It seems worthwhile to again examine the data presented by Wilson and Meyer (1972, 1982) and Wilson and Hahn (1973) in a somewhat different light in order to defend the opinion that *Micrurus ruatanus* is a distinct species.

Wilson and Meyer (1972) examined variation in *M. nigrocinctus* in Honduras in detail and concluded that recognition of subspecies in Honduras is unwarranted. They pointed out, however, that "specimens from northern Honduras generally are bicolor and have a *low number of black body bands* (italics mine) and ventrals and a long pale head band." The italicized portion of the above-quoted remarks calls into question Roze's (1982) remark about high black body bands in "some" northern species. This comment ignores much of what Wilson and Meyer (1972) had to say, i. e., that the northern bicolor populations exhibit a morphocline in the amount of deposition of black pigment on the red body bands extending from a condition where such pigment is absent or restricted to a few scattered scales through five intermediate stages to one in which the black pigment on the red bands has coalesced into a band indistinguishable from the other black body bands (i. e., the condition exhibited by TCWC 21181). Thus is explained the purported but spurious "approach" toward the condition of high black body band counts in "some" specimens from northern Honduras. Other specimens from the remainder of the country have black body band counts ranging from 11-24, $\bar{X}$ = 17.4, (the figure of 27 given for a male specimen, LSUMZ 21773, from population D in Wilson and Meyer, 1972, is incorrect; the correct count is 14; the number 27 was inadvertently obtained by adding the number of pairs of black blotches in the red band area, Fig. 5A in that paper). That range does not closely approach the counts for *M. ruatanus*.

Micrurus ruatanus was discussed and described by Wilson and Hahn (1973) and Wilson and Meyer (1982). These authors pointed out the high numbers of black body bands, ranging from 33 to 45 ($\bar{X}$ = 38.9). There is no overlap in the ranges of black body band counts between *M. ruatanus* and *M. nigrocinctus*, even counting the "double-banded" TCWC 21181. The means are separated by approximately *22* scales! There is also a noteworthy distinction in the *nature* of the banding. In the northern Honduran mainland populations of *M. nigrocinctus*, the accretion of black pigment in the red body bands acts to produce rounded blotches which, in one specimen, have coalesced into complete bands. In *M. ruatanus*, however, the black bands in some specimens are of two types, viz., longer complete bands and narrower disrupted bands that alternate with one another, most conspicuously on the posterior portion of the body (Wilson and Hahn, 1973). Ventral numbers also range lower in *ruatanus* than in *nigrocinctus* from Honduras (Wilson and Meyer, 1972). Male *ruatanus* have 183-185 ventrals; males of *nigrocinctus* from Honduras have 190-208. Females of *ruatanus* have 193-203 ventrals; female *nigrocinctus* from Honduras have 206-224. *Micrurus ruatanus* is, finally, a smaller coral snake than *M. nigrocinctus* from Honduras, especially those from the north coast. The largest known *ruatanus* (LSUMZ 22341) is a female with a total length of 681 mm; the largest *nigrocinctus* (MCZ 33342) from Honduras is 1194 mm in total length (not 1076 mm, as indicated by Wilson and Meyer, 1982). The latter specimen is from Lancetilla on the northern coastal plain.

It is evident that *Micrurus ruatanus* is a coral snake differing conspicuously from *M. nigrocinctus* in having a higher, non-overlapping black body band count, a distinct color pattern morphocline, lower ventral numbers, and a smaller body size. On the basis of the distinctiveness of these features, it is my opinion that *Micrurus ruatanus* deserves specific status.

OBSERVATIONS OF THE FEEDING HABITS OF THE SHORT-TAILED SNAKE, *Stilosoma extenuatum* IN CAPTIVITY

Knowledge of the natural history of the short-tailed snake, *Stilosoma extenuatum*, is limited. It is certainly one of the least studied serpents in North America. Carr (1934) noted this species' power of constriction and remarkable muscular control and placed *Stilosoma* on par with kingsnakes as a constrictor and ophiophage. Ditmars (1939) reported that two captive *Stilosoma* killed and ate small brown snakes *(Storeria)* by constriction but refused small lizards. Allen and Neill (1953) reported short-tailed snakes kill prey by constriction and prey upon lizards and other unspecified snakes. Other than these few reports, the ecology of the short-tailed snake is unknown. Here I report on the results of 39 feeding trials with a single individual.

MATERIALS AND METHODS

An adult male with a snout-vent length of 540 mm was collected in Hillsborough County, Florida, on 21 February 1983. The snake was maintained in a 50 l aquarium in about 2 cm of local sand. Room temperature

ranged from 17 to 23° C. Water and refuge were always available. The feeding habits of this snake were closely monitored while offering it nine different prey species over a seven month period. Prey were offered to the *Stilosoma* every 8-12 days between 1000 and 1500 h and continuously observed for 60 min. If the *Stilosoma* did not attack or pursue the prey in that hour the prey was allowed to remain for 24 hours. If at the end of the 24 hour period the first prey species was still alive, it was replaced by a Florida crowned snake, *Tantilla relicta*. Again, I watched the snake closely for 1 hour. If the *Stilosoma* did not attempt to follow or inspect (tongue flick) any offered prey species during the first 30 minutes of observation, I carefully restrained the prey with forceps and allowed the *Stilosoma* an opportunity to examine the prey as I held it about 5 cm away. Continued lack of interest would result in that prey remaining in the snake cage for 24 hours. If the *Stilosoma* became interested in the prey I would release it near the snake. Prey species are listed in Table 1.

RESULTS

Ten of 16 successful feeding bouts are summarized in Table 2; six prey were ingested at night and not witnessed. Two additional bouts were observed but the prey ultimately escaped. Only *Tantilla relicta* was ingested by the *Stilosoma*. On several occasions the short-tailed snake showed interest in, but never attacked, other prey species, mostly snakes.

Generally the *Stilosoma* would begin a feeding bout with a *Tantilla* by directing and increasing the rate of tongue flicks. Nine of twelve attacks occurred as the *Tantilla* moved past the *Stilosoma*. The *Stilosoma* trailed the *Tantilla* in the remaining three. The position of the first bite and the method of killing (ingestion or constriction) influenced the total handling time. If the first bite was within 10 mm of the head, ingestion would begin in about 20 min. whereas a more posterior bite would considerably increase the (pre-ingestion) handling time.

Constriction was used to restrain a *Tantilla* on 4 occasions. The first is reported as feeding bout 2 in Table 2; two others were unsuccessful attempts at predation that lasted in excess of 120 minutes. During the 9th observed feeding bout (Table 2) constriction was used to hold the *Tantilla* for 30 min, but eventually the body hold on the prey was released and the *Tantilla* was restrained by the bite until ingested.

DISCUSSION

My observations, like those of Ditmars (1939), suggest that *Stilosoma extenuatum* is strictly ophiophagous specializing on Florida crowned snakes. It does not seem to be interested in lizards (contrary to Allen and Neill 1953) including those sand-swimming lizard species that are specialized for syntopic existence in the Florida sandhills.

Killing by constriction appears very costly in terms of time and energy when compared to ingestion of live prey. Carr (1934) watched an adult male take two hours and fifteen minutes to kill and eat a *Tantilla*. My three observations of *Stilosoma* attempting to kill a prey snake by constriction all extended beyond 2 hours and two of the bouts terminated as the *Tantilla* escaped.

When constricting a *Tantilla* the *Stilosoma* would use the anterior third of its body to wrap three coils around the prey and then proceed to stretch the *Tantilla* between the coils and its more anterior bite. From this posture the *Stilosoma* would "walk" its bite anteriorly on the *Tantilla* as it pulled the posterior portion of the prey in the opposite direction, appearing to injure the prey snake. The actual form of the constriction behavior was very similar to what Greene and Burghardt (1978) termed the boid pattern of constriction. The *Stilosoma* would seize the prey and with an initial twist in the first loop, turn about its long axis as it applied the loops to form a horizontal coil. Thus, the coil was applied with the anterior portion of the predator's body in such a way that the *Stilosoma's* venter faced its head. However, as a precautionary note, Greene and Burghardt (1978) found intergeneric, intraspecific and individual variability in coil application movements within the colubrid snakes.

A statement about the evolutionary implications of a relatively small reptile (with a limited size range of prey) becoming such a highly specialized predator seems in order. According to Smith (1982) *Tantilla relicta* feeds almost exclusively on Tenebrionidae larvae (89.6% of 270 prey from 124 stomachs). Tenebrionids and *Tantilla relicta* are exceedingly abundant in the patchy sandhills of central Florida. Mushinsky (unpubl. data) used pit-fall traps to collect over 150 *Tantilla relicta* (in 12 mo) on approximately 20 ha. of sandhill habitat. A logical conclusion regarding this food chain is that it reflects a long-term stability that has allowed natural selection to produce these highly stenophagic snakes. It is, however, paradoxical that we find such a well defined trophic relationship in a habitat that is itself dependent upon fire and other disturbances for its own survival. Campbell and Christman (1982) stated that the reptile community occurring in the sandhills of Florida does not actually respond to a particular plant association but rather to the physical structure of the habitat (i.e. dry, well-drained with patches of open sand). Additional field studies of this rapidly disappearing sandhill community are necessary before we can make any definitive statements regarding trophic relationships.

DISEASE STUDIES AID KEMP'S RIDLEY SEA TURTLE HEADSTART RESEARCH

Since 1977, the Southeast Fisheries Center's Galveston Laboratory, (NOAA National Marine Fisheries Service) has been conducting sea turtle headstart research. Kemp's (Atlantic) ridley sea turtles *(Lepidochelys kempi),* designated an endangered species by the U.S. Endangered Species Act of 1973, are raised in captivity during their first year of life and then are tagged and released at sea in hopes that they will continue their growth to adulthood. Analysis of the results of this project will assist to determine if headstarting can augment the natural nesting populations of the Kemp's ridley (Klima and McVey 1982).

In nature, Kemp's ridley hatchlings are highly vulnerable to mortality, primarily through predation. Turtle biologists have estimated that less than 5 percent of these hatchlings survive through their first year. With headstart techniques, about 68 to 95 percent survival has been achieved with captive turtles during this critical first year.

Kemp's ridley hatchlings are supplied to the Galveston Laboratory through the cooperative efforts of the Instituto Nacional de Pesca, Mexico, the U.S. Fish and Wildlife Service, and the U.S. National Park Service. They are reared for 7 to 12 months and those in good condition are tagged and released off Padre Island, Texas (earlier release sites included the west coast of Florida) (J. P. McVey and R. S. Wheeler, pers. comm. 1978-1981). Also, approximately 86 headstarted yearlings of the 1978 and 1979 year-classes have been distributed to Miami Seaquarium in Miami, Florida, and Sea Arama Marine World in Galveston, Texas, to provide a potential captive brood stock (R. S. Wheeler, pers. comm. 1981). Of these turtles, 8 are still surviving at Miami, and 10 at Galveston (F. H. Berry and R. M. Harris, pers. comm. 1983).

At the beginning, loggerhead *(Caretta caretta)* hatchlings rather than Kemp's ridley hatchlings were reared so that the Galveston staff could gain experience for future application to the endangered ridleys. In September 1977, 1,160 loggerhead hatchlings, obtained soon after hatching from eggs collected by the Florida State Department of Natural Resources, Jensen Beach, Florida, were shipped to the Galveston Laboratory. These hatchlings were reared communally in large close-ended concrete tanks (raceways), containing recycled natural seawater, and originally designed for shrimp culture (C. R. Mock and C. T. Fontaine, pers. comm. 1977). Later, many culture methods were developed and used, including flow-through tanks in which the seawater was constantly and gradually exchanged through a supply valve and a drainage outlet (A. Brown, Jr. and R. S. Wheeler, pers. comm. 1977). The animals were fed mainly a frozen fish diet.

The decision to experiment first with the loggerheads proved to be quite beneficial. Although there was only a 9 percent loggerhead survival, by the end of the 10-month rearing period the staff had learned much about turtle diseases and their prevention and treatment. Almost 100 percent of the loggerhead hatchlings became ill at one time or another and many died. The most serious kind of death (about 40 percent) involved a "sudden hatchling death" (SHD) syndrome in which the animals suddenly died without any discernible cause. Other commonly occurring diseases were skin and shell lesions, eyelid infection, emaciation, bowel obstruction, and anal infection (Leong 1979). Mortality due to SHD rapidly dropped from a peak of about 4 percent to about 0.2 to 0.3 percent per day when the turtles were transferred from the closed raceways to flow-through tanks. However, the other diseases appeared one after another.

Laboratory work indicated that the primary requirements for disease treatment and control were clean water and individual isolation of sick turtles. Both requirements were met by holding individual sick animals in plastic 10-liter buckets containing seawater, which was changed daily. When necessary, therapeutic drugs or antibiotics were administered topically, by intraesophageal intubation or by subcutaneous injection. The development of isolation techniques and chemotherapy led to the recovery of many sick turtles. A successful therapeutic treatment involved the use of static formalin bath in conjunction with injections of an antibiotic such as ampicillin or chloramphenicol.

During July and August 1978, the first shipment of 3,081 Kemp's ridley hatchlings was received at the Galveston Laboratory. The turtles were reared together in large, communal, fiberglass raceways. Water was changed completely three times weekly. The turtles were fed a commercial pelletized feed.

Every turtle contracted diseases or infections of one kind or another. Some illnesses were similar to those we had experienced with the loggerheads, but there were also many new diseases. In addition, the ridley hatchlings were extremely aggressive, and soon after being placed in the raceways most suffered injuries caused by either biting or scratching each other. Such aggressive behavior was not observed in the loggerheads.

Most of the diseases and injuries in the 1978 year-class of ridleys were successfully controlled through isolation and treatment techniques as previously established for loggerheads. However, the maladies recurred after the ridleys were returned to the communal raceways. Experiments showed that biting and wounding could be eliminated and turtle disease vastly reduced by isolating each hatchling in individual containers within the raceways. Therefore, in subsequent rearing practices, individual turtles were isolated in perforated buckets suspended in the raceways. Survival rate for the 1978 year-class was 68 percent.

Bowel compaction was common among the hatchlings of the 1977 and 1978 year-classes. In attempts to develop a diagnostic tool for this condition, a cooperative effort was launched (with Dr. G. L. McLellan) to explore the use of x-ray technology. Tests showed that the barium-fluoroscopic method, normally used on humans with gastrointestinal problems, produced good quality x-ray films of the gastrointestinal tracts of healthy hatchlings (McLellan and Leong 1981). This result indicated that x-radiography was potentially useful for diagnosing intestinal obstructions in sea turtle hatchlings.

Kidney infection was another malady requiring internal diagnosis. We tried, unsuccessfully, to develop radiological diagnostic techniques, using radio-opaque material. We learned from this trial, however, that subcutaneous injections of a radio-opaque material, sodium diatrizoate, administered to the neck region, were absorbed much faster than those administered to the suprafemoral pouch (referred to as "hind limb" in McLellan and Leong 1982), as was the general practice in parenteral administration of drugs for disease treatment in turtle hatchlings. This finding suggested that injection of drugs into the neck area for disease treatment was probably more effective than injection into the suprafemoral pouch (McLellan and Leong 1982).

In 1979 and 1980, prevention and treatment of diseases in ridleys contributed to survival rates of 83 and 95%, respectively. During this time, however, an outbreak of a bloating syndrome affected more than 300 ridley hatchlings, killing about 150 of them. Autopsies revealed that the animals had duodenal ulcerations. Follow-up clinical observations and feeding experiments showed that a modification of feeding regimens, either by reducing the amount and frequency of feeding from 4 times to 2 times per day or less, or by replacing the manufactured turtle feed with a ground fish diet, were successful in stopping the spread of the bloating, and led to the recovery of the sick turtles.

The 1,865 ridley hatchlings received in 1981 did not fare nearly as well as the 1980 year class. From the outset, the 1981 year-class was plagued with at least two kinds of fungal infections. The first type surfaced in August 1981 shortly after the hatchlings arrived at the Galveston Laboratory. Autopsies revealed a hardened yolk sac, heavily infested with fungal spores and mycelia. Three different fungi were isolated in laboratory cultures. One, *Paecilomyces* sp., was suspected to be a pathogen. More studies will be needed to confirm the pathogenicity of the isolated fungi. In slightly older hatchlings, a similar type of fungal infection, also apparently associated with *Paecilomyces*, was found in the liver, lung, muscle, and brain. To date, there has been no effective treatment for the *Paecilomyces* type infection, but circumstantial evidence suggested that sunlight could be helpful in curing head lesions infected by the fungus. Generally, infected hatchlings show few external signs or symptoms that can be used for early diagnosis, although in advanced stages of the disease, sick turtles are emaciated and stunted in growth.

Another type of mycotic infection in the 1981 year-class involved the fungus *Scolecobasidium constrictum.* The primary site of infection was in lung tissue, but the fungus was also observed to damage bone tissue. The disease usually did not become apparent until the affected turtles were 6 to 7 months old. So far, we have not found a cure. By providing the sick animals with a clean and warm environment during clinical isolation, however, we have been able to obtain spon-

taneous recovery in some cases. In June 1982, the survival rate of the 1981 year-class prior to release was 79%.

We have not determined whether the diseases occurring in captive sea turtles also occur in the wild, or if they are peculiar to the conditions of rearing sea turtles at the Galveston Laboratory. Nevertheless, it is clear that successful disease prevention and treatment have contributed greatly to the high survival rates experienced with these animals in captivity during their first year of life. Such success has led to the release of larger numbers of healthy, yearling Kemp's ridley sea turtles, which we hope will contribute significantly in the years ahead toward the conservation of the species. The Galveston Laboratory has continued with sea turtle pathology research to try to improve techniques and methods for diagnosis, prevention, and treatment for diseases and injuries in sea turtles.

THE ESTABLISHMENT OF *Podarcis muralis* IN CINCINNATI, OHIO

Several species of European animals have been purposely and accidentally released in the United States. Among the earliest planned introductions were those that occurred during the years 1872-1874, when 4000 individuals of 20 European birds were imported to Ohio for release in Cincinnati (Langdon 1881). This attempt by the Acclimatization Society of Cincinnati to increase the number of Ohio songbirds ended in total failure. Not even the European starling, *Sturnus vulgaris*, survived, although the species later spread through most of the United States following its successful 1890 and 1891 introductions in New York City (Long 1981).

Exact dates of accidental introductions are more difficult to determine. For example, the European lizard colonies *(Podarcis sicula* and *Lacerta viridis)* in Topeka, Kansas, were probably established in the 1950s from specimens that escaped from an animal dealer (Collins 1982). Conant (1945) reported the occasional appearance of various European lizards on the piers and grounds of a cork import company in Gloucester, New Jersey. While none of the four observed species succeeded in establishing themselves in Gloucester, one of them, *Podarcis muralis*, did succeed when it was deliberately introduced in Cincinnati.

In September 1951, following a family visit to Europe, a Cincinnati resident brought two European wall lizards, *P. muralis*, to the United States. The animals had been caught in the Lake Como area of northern Italy, and were released in the backyard of the resident's Cincinnati home. The *P. muralis* population has since spread throughout much of southeastern Cincinnati. The purpose of this note is to outline the possible reasons for the success of this European wall lizard transplantation.

Hundreds of European plant and animal species have been established in North America, but relatively few have invaded native habitats. The vast majority occupy cultivated and urban areas, new habitats that humans introduced to North America (Elton 1958; MacArthur 1972). Indigenous American species did not have time to colonize these manmade habitats before the arrival of such immigrants as chicory, *Cichorium intybus*, dandelion, *Taraxacum officinale*, cabbage butterfly, *Artogeia rapae*, Norway rat, *Rattus norvegicus*, and starling, *S. vulgaris*. These species succeeded in their new American environments because they were already adapted to living alongside humans in towns and fields of Europe.

The wall lizard, *P. muralis*, is a good example of an animal that lives in association with human habitations in Europe. It seems likely that *P. muralis* evolved in dry, rocky regions and that it spread into many of the areas it now occupies subsequent to human agricultural and construction activities. In Europe, I have observed wall lizards on stone walls, sides of houses, piles of rocks, and railway embankments. According to Arnold and Burton (1978), *P. muralis* is the most urban Lacertid in Europe.

The two wall lizards transplanted to Cincinnati in 1951 (not 1948 as reported by Vigle 1977) were released on a stone wall. Their descendents have since spread to limestone rock outcrops and all of the same urban habitats as those listed above in Europe. The wall lizard's ability to adapt to the Cincinnati environment is largely due to pre-adaptation in its original range.

In addition to suitable habitat, lack of competition is another obvious criterion for the success of imported species. *P. muralis* has not had to compete with native lizards in its present 6 km² Cincinnati range. The eastern fence lizard, *Sceloporus undulatus*, five-lined skink, *Eumeces fasciatus*, and broad-headed skink, *E. laticeps*, occur in the Cincinnati region (Conant 1951), but none of these species inhabit the area that has been colonized by *P. muralis* since 1951.

Another European species, the starling, *S. vulgaris*, is also found throughout the area now occupied by *P. muralis*. Like the wall lizard, the immigrant starling is pre-adapted to an urban habitat and meets with little competition from native animals (Forbush 1920). But unlike the wall lizard introduction, the deliberate transplantation of foreign-born starlings to Cincinnati was unsuccessful, possibly due to climatic differences between the starlings' native localities and Cincinnati (Roots 1976).

Unlike the initially unsuccessful starlings, the wall lizards from Italy's Lake Como region were probably better pre-adapted to Cincinnati's climate. Similar temperature and precipitation patterns occur in Cincinnati and Milan, the meteorological station nearest Lake Como, 40 km distant (Fig. 1). The average monthly temperature is 13.3 ° C in Cincinnati and 12.8 ° C in Milan. The average-monthly precipitation is 82 mm in Cincinnati

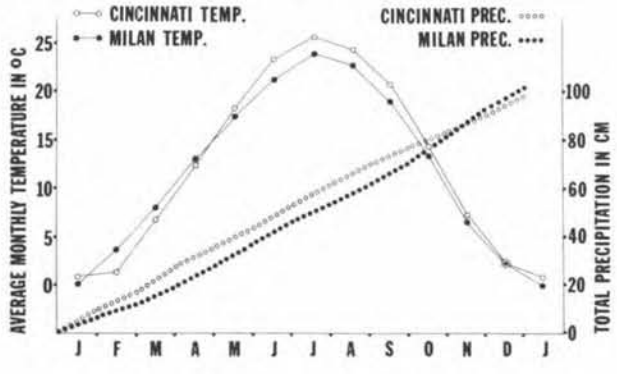

Figure 1. Temperature and moisture patterns of Cincinnati, Ohio and Milan, Italy (data from Miller 1961).

and 84 mm in Milan (Miller 1961). The similarities of climate and habitat between the European place of origin and the American site of introduction are probably the major factors that allow *P. muralis* to survive in Cincinnati.

A New Reprint

HERPETOLOGY OF ARABIA

by John Anderson

with an extensive introduction by Alan E. Leviton and Michele L. Adrich
including a new checklist of Arabian amphibians and reptiles

In 1896 John Anderson published the book *A Contribution to the Herpetology of Arabia, with a Preliminary List of the Reptiles and Batrachians of Egypt*, a pioneering effort to summarize the herpetology of those regions and, to this day, the only herpetology of the Arabian Peninsula. The original book is exceedingly rare, probably published in an edition of no more than 100 copies, and is much less known than Anderson's major work on amphibians and reptiles in the *Zoology of Egypt* series. The Arabian book includes a description of the physical features, a review of the amphibians and reptiles of the Arabian Peninsula including Yemen, an exhaustive bibliography of the herpetology of Arabia, and a checklist of species both of Arabia and of Egypt including the Sinai. This reprint includes a new introduction with a biography and portrait of Anderson, a list of his publications and an up-to-date checklist of the herpetofauna of Arabia, with map. The book is 160 pages, 6 x 9 inches (15.5 x 23 cm), and bound in buckram; there is one plate in full color.

TO ORDER

SSAR members, if ordered *before 30 November 1984* ..... US $18
Institutions; Non-members; All orders after 30 November ..... US $24

SSAR members must place their orders now to take advantage of the special pre-publication price. The book will be published in December 1984. Send orders to Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA. Please make checks payable to "SSAR". All USA orders are postpaid; shipments outside the USA will be charged only the *additional* shipping costs in excess of domestic rates. Overseas customers must pay in USA funds or by International Money Order, or may charge to MasterCard or VISA (give account number and expiration date). A complete list of Society publications and membership information can be obtained from Dr. Taylor. The Society publishes *Journal of Herpetology, Facsimile Reprints in Herpetology, Herpetological Review, Herpetological Circulars, Catalogue of American Amphibians and Reptiles, Contributions to Herpetology*, and *Recent Herpetological Literature*.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Where the animals roam . . . Physiological Zoology

From chloride transport in freshwater mussels to digestive efficiencies of wild howler monkeys, from sweat gland secretion in the black Bedouin goat to respiratory physiology of freely diving harbor seals — **PZ** remains one of the few journals concerned with whole organisms and animal populations as well as with cellular mechanisms.

Offering increasing numbers of comparative physiologists and physiological ecologists the research that is shaping the field, **PZ**'s scope encompasses all aspects of physiology:

–water and ions
–respiration
–metabolism
–temperature
–biochemistry

Physiological Zoology, now bimonthly. Edited by C. Ladd Prosser and James E. Heath.

One-year rates: Individuals $38.00; Institutions $65.00; Students with copy of ID $25.00. Outside USA add $3.00. Visa or MasterCard accepted. Send complete charge card information, purchase order, or payment to The University of Chicago Press, P.O. Box 37005, Chicago, Illinois 60637.

TECHNIQUES

A MODIFIED SEINING TECHNIQUE FOR SINGLE PERSON SAMPLING OF DEEP OR COLD WATER

Seining is the most successful and widely used method of sampling small bodies of water for aquatic vertebrates. Two drawbacks of seining are 1) two people are required to operate the seine, and 2) the operators must enter the water, making cold or deep water difficult to sample thoroughly. In order to conduct a study of *Ambystoma tigrinum*, a salamander found in ponds which are sometimes too deep or cold for ordinary seining methods, I developed the technique described below.

An ordinary seine is modified as shown in Figure 1A and 1C. Eye bolts are attached to each brail by drilling holes through the pole near the lead-line end, threading the bolts through, and attaching hexagonal nuts to secure the bolts. Flat washers should be used to protect the brail and lock washers will prevent accidental loosening with use. Figure 1B depicts an alternative method of brail modification. A weight (e.g. 2.8 kg of lead shot in a sturdy canvas bag) is attached to the bottom eyebolt of each brail. The weights serve to submerge the seine, therefore their heaviness will vary with the size of the brails and the buoyancy of the float line. A separate tow rope is connected to each brail by the eyebolts at a particular level. Attachment of weights and tow ropes can be done with sturdy metal clips to facilitate their repeated removal, since it is easier to carry the seine and equipment separately.

After the weights and tow ropes are attached, the seine can be used in two ways. If two people are available, each person can tow one rope with the seine extended between them. If the ropes are long enough a pond can be straddled and the samplers need not enter the water. I have successfully used this method (with two 30 m ropes) to seine Nebraska cattle ponds, since these bodies of water usually lack trees and other shoreline impediments.

When portions of the shoreline are obstructed or only one person is available, the following alternative method can be used: The seine is stretched along one shore parallel to the opposite side. Tow ropes are extended across the pond by carrying them around or by tying a strong lightweight cord to the rope, throwing the cord across the pond by means of an attached weight, and pulling the rope across with the cord. (The latter is helpful when tall vegetation is found near the shore). On the opposite shore each rope is inserted through one of two metal loops which have been screwed into the ground a seine-width apart. Dog-leash tie-outs, which can be purchased at most pet stores, work best. These loops serve to hold the ropes apart and close to the ground, keeping the seine extended and helping to prevent "hopping" (repeated lifting of the lead line off the bottom). The operator can then tow the seine across the pond by pulling the ropes

simultaneously, either hand over hand or by holding on and walking away. I am approximately 1.8 m tall and weigh 79.5 kg, and have been easily able to tow a 10 m by 2 m bag seine of 1 cm by 1 cm mesh. On occasions when the seine has become caught on underwater obstacles, releasing one rope and pulling on the other has never failed to free the net.

I have found that this method is most successful with bag seines. The brails tend to lean backward as they are being pulled and the bag captures organisms that would be washed over the float line of a normal seine. This problem can be alleviated by towing normal seines more slowly, by attaching the tow ropes at a higher level, or by firmly attaching styrofoam floats to the tops of the brails.

The above seining modifications are especially useful for sampling small ponds which are normally too deep and/or cold to enter. For example, in order to capture reproductive *Ambystoma tigrinum* (which are explosive breeders in late winter) it has previously been necessary to surround entire ponds with drift fence, which requires time-consuming maintenance and frequent nighttime surveillance. Seining allows the frequent sampling of numerous winter ponds without debilitating immersion. In addition, I have been able to collect fish, neotenic salamander larvae, and overwintering frogs from ponds deeper than 7 m. I doubt that this technique will be useful on any but the most sluggish of lotic waters, and I have only attempted to use it on ponds, stream backwaters, and dammed creeks. However, biologists working in the latter environments may be able to use this modified seining method to increase their sampling productivity.

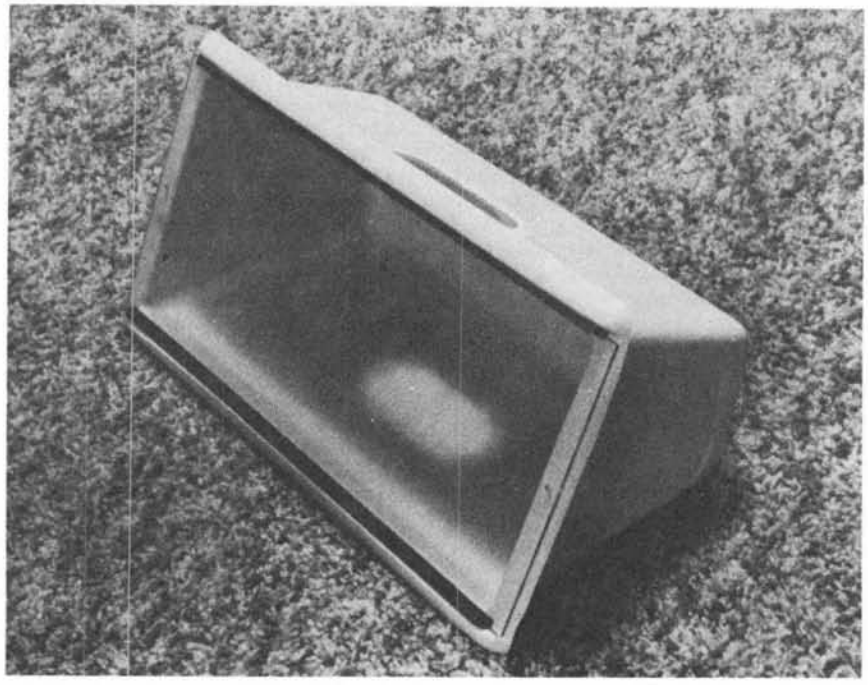
A TAGGING METHOD FOR USE IN HATCHLING TURTLES

It is important in laboratory studies of behavior and growth of hatchling turtles to be able to identify individuals (reviewed by Plummer 1979). Toe clipping and scute notching (Cagle 1939), marking with waterproof pens (Sarnat and McNabb 1981), lacquered ink (Miller 1955), and insertion of plastic buttons (Pough 1970) have all been used with success. However, in turtles with dark shells, the marking pen and similar techniques are not effective. The scute notching and toe-clip techniques require handling the animals to obtain a positive identification, and if not applied properly, the shell notching may either heal over completely or seriously deform the animal as it grows (Cagle 1939). The use of "Buttoneer" tags (Pough 1970) may not be possible in hatchling turtles until the posterior marginal portions of the carapace are ossified and the animal can withstand a hole being drilled into its carapace. Here we describe a simple method of marking hatchling turtles using plastic beads tied through pierced posterior carapacial scutes, which allows individual identification without handling. This technique is similar in some ways to those devised for marking individual amphibians (Nace and Manders 1982) and reptiles (Pough 1970).



METHODS

Each tag consisted of a pair of colored plastic beads tied together through a pierced posterior marginal carapacial scute. Color combinations were selected for individual identification. The tags were prepared beforehand by tying one of the plastic beads (approximately 2.5 mm in diameter, 1.5 mm in thickness) securely with a reef knot onto the middle of a piece of monofilament nylon or polyester thread at least 15 cm in length. In the present study, two regimes of tagging were implemented. Seventy-five hatchling snapping turtles *(Chelydra serpentina)* were tagged in the initial study by tying the monofilament threads with a reef knot. A subset of 61 turtles was blotted dry on paper towelling and weighed, tagged, and immediately reweighed. In a second experiment, 26 turtles were tagged. Sixteen tags were tied and then the knot was melted with a fine soldering pencil; the remaining 10 turtles' tags were tied, but the knot was not melted.

The turtles were placed into cold torpor prior to tagging. The dorsal and ventral posterior margins of the carapace were swabbed with alcohol. A posterior marginal scute was selected and pierced from below with a short, fine-gauge hypodermic needle. The free ends of the tag threads were passed through the needle, from the point side, while it was still protruding through the shell. The needle was then withdrawn, leaving the threads through the carapace, hanging free on the underside. The threads were gently pulled to bring the upper bead against the carapace, and the lower bead was then threaded and tied. The trailing ends of the threads were trimmed to within 4 mm of the knot. If trimmed more closely, the tag tended to become untied after awhile.

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16'' thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24'' Reptile Cage $29.95

24'' Wide, 12¼'' High, 12½'' Deep
Approx. 250 sq. in. floor area
Single Vent

36'' Reptile Cage $53.95

36'' Wide, 18'' High, 19'' Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges. $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

RESULTS AND DISCUSSION

Most turtles tagged in this fashion ignored the tag completely, but some pushed against the lower bead with the nearest hind foot, and some snapped at tags on others, especially brighter tags in warm colors. It did not appear that the tagging techniques caused any mortality among the hatchlings, although this was not controlled for. The turtles weighed significantly less after tagging (prior to tagging, $\bar{X} = 7.09 \pm 1.84$ g; after tagging, $\bar{X} = 6.85 \pm 1.67$ g; paired $t = 13.28$, $P < 0.0005$, $n = 61$). The tags themselves weighed very little ($\bar{X} = 0.02785 \pm 0.00701$ g; $n = 20$), and the difference in hatchling weights before and after tagging was attributed to water lost during handling. The turtles in the first study (monofilament thread not fused) were maintained at 26° C for 69 days. During this time, 14 hatchlings died, and 17 lost tags at least once. Tags were lost in two ways: either the knots untied or the tag broke through the remaining portion of the scute. On average, 2.5% of surviving turtles lost tags each week. Five hatchlings were observed beyond 10 weeks and none of these lost the bead tags over the next 10 months.

Animals in the second study were maintained at room temperature for 7 weeks. During this period, two of the 26 turtles died, one of the 10 tied-only animals lost its tag (10%), and two of the 16 fused-knot tags were lost (12.5%). Occasionally the threads would be cut by the soldering pencil while tagging, and the whole process had to be repeated (five of 16 tags). Therefore, although the two techniques had very similar loss rates during this brief study, the problems with tagging caused by trying to melt the threads without burning the animal or cutting the threads would suggest that tying alone is sufficient.

This technique facilitates positive identification of individual turtles without handling, as long as both beads can be seen. The relatively high tag-loss rate (2.5% per week), as compared to similar techniques (Nace and Manders 1982) may be attributed to the incompletely ossified posterior carapace in hatchling turtles. The use of a wire implant through a bone such as a humerus or femur (Nace and Manders 1982), although perhaps less likely to be lost than a threaded tag, may cause serious injury to an animal less capable of regeneration than an amphibian. It is not known if the present technique could be used in a field-marking situation, but it is possible that if the beads were tied on with enough slack, growth to adult size could be accommodated.

PAINT-MARKING THE RATTLE OF RATTLESNAKES

The explicit statement of Tinkle (1979) emphasizes a need for long-term field studies based on marked individuals in populations. Despite an obvious need for a uniform marking technique for each major species group of amphibians and reptiles, methods have become so numerous as to allow recent reviews of them (Spellerberg and Prestt 1978; Swingland 1978; Ferner 1979). No single marking system yet seems to be accepted as ideal for all members of a given group.

In rattlesnakes (genera *Crotalus* and *Sistrurus*), several workers describe temporary marking techniques of the rattle itself (copper wire, Fitch and Glading 1949; colored discs, Pendlebury 1972) or tail near the rattle (colored beads, Hudnall 1982). The rattle is a logical place to mark the animal because of its conspicuousness and relative permanence from year to year. We here describe a practical and simple technique for marking the rattle of rattlesnakes: paint it. Our method has the major advantage of being quick and easy to us in the field or lab.

Our painting technique is done by applying permanent water-proof paint to the basal segments of the rattle and distal portion of the tail. We have paint-marked *Crotalus viridis* since 1976 (Gannon, Secoy) and *C. horridus* since 1978 (Brown). Paint may be applied by spraying (Gannon and Secoy 1984) or by dabbing (Preston 1964; Brown, unpublished). In dabbing paint on the rattle, we recommend using "Liquitex®," an acrylic artists' paint (Binney & Smith, Inc., Easton, Pennsylvania 18042) available in a variety of bright colors. The paint is mixed with water to get the desired consistency and is dabbed on the rattle using a small wooden applicator. After drying, this paint is permanent, flexible, waterproof, and long-lasting. Paint-marks have remained visible on rattles of recaptured *C. horridus* for up to four years.

Paint-marking is especially valuable when used with a permanent mark for individual identification (e.g., ventral scale clipping, Brown and Parker 1976). Major advantages of paint-marking are the following (cf. Fitch 1949, and Pendlebury 1972, who noted the first advantage, and Preston 1964 and Gannon and Secoy 1984, who noted the first two):

1. Shedding frequencies may be directly and accurately measured; the number of unpainted basal segments added to the rattle indicates the number of sheds in the interval between captures. The shedding rate is a powerful datum in estimating the age of rattlesnakes when used with growth increments of recaptured individuals. (Incidentally, shed skins of freshly painted snakes occasionally may be found in the field and these can be identified both by the intact paint and scale-clip scars.)

2. Each separate study population may be identified by a different color. If recaptures occur away from release locations (after individuals have moved or dispersed), spatial overlap of snakes from different locations may be recorded. Also, by color-coding each locality, accidentally releasing marked snakes at the wrong place is avoided.

3. Sometimes only glimpsing an escaping rattlesnake is possible; when visual sightings occur, a painted rattle usually may be seen and its color noted, thus reducing the need to exert an all-out capture effort when the snake has gotten away. At least it will be known to be marked.

4. When a number of snakes are measured, weighed, and marked at one time, freshly paint-marked individuals are easily distinguished from unpainted individuals when both are temporarily put together in a single holding container. This makes sorting and handling more efficient and less traumatic to the snakes.

5. Paint on a rattle will be noticeable to a layperson who might happen to see a marked animal, find a dead specimen, or kill a marked snake. A specimen may thus be saved and turned in to wildlife personnel, providing a record of a marked animal whose loss from the study population otherwise may never be known to the investigator. Also, in cases where rattlesnakes are the deliberate targets of a human predator seeking an epidermal souvenir, the indissoluble colored paint may make the rattle a sullied and therefore less desirable "trophy."

The very simplicity of the rattle-painting technique perhaps has been one reason why heretofore, to our knowledge, it has not been formally described. Paint-marking should be applicable to any field study of a rattlesnake where shedding rates and age estimation form the foundations of long-term natural history and demographic research.

ACKNOWLEDGMENTS

Funding to Brown was provided by a federal endangered species Grant in Aid Agreement (NY-E-1) with the New York State Department of Environmental Conservation for status surveys, culminating in full statewide legal protection of *C. horridus;* support from the National Geographic Society (Grants 2590-83, 2823-84) assists current ecological work on this species. Field and laboratory assistance have been provided by Randy Stechert and Tommy Davis.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

ANURA

CENTROLENELLA FLEISCHMANNI (Glass Frog). BELIZE: CAYO DISTRICT: 7.1 km SSE Belmopan. 4 July 1980. R. E. Olson. REO 5540-5542. Verified by R. E. Olson. To be deposited in St. John's College, Belize City. The frogs were collected as they called from palm fronds above the banks of a rushing stream. Second record for Belize; extends range about 30 km NE San Luis, Cayo District (Henderson and Hoevers. 1975. Milwaukee Publ. Mus. Contr. Biol. Geol. 5:13).

Submitted by **R. EARL OLSON,** Department of Biology, Cornell College, Mt. Vernon, Iowa 52314, U.S.A. (present address: 133 S. Cleveland, Cambridge, Minnesota 55008, U.S.A. ●

HYLA CHRYSOSCELIS (Cope's Gray Treefrog). USA: MINNESOTA: Hubbard Co: 12.8 km S Lakely. 20 June 1981. R. E. Olson Collection (REO 5688). Isanti Co: Springvale. 20 June 1970. REO 2977-2978; 30 June 1972. REO 3369-3370. 1.8 km W Cambridge. 25 May 1980. REO 5408-5411. 13.3 km NW Cambridge. 21 June 1983. REO 6205-6206. Kandiyohi Co: 1.2 km E Sunburg. 3 June 1980. REO 5428-5430. 3.8 km E Sunburg. 3 June 1980. REO 5431-5432. 14.8 km W New London. 3 June 1980. REO 5433-5434. 18.7 km E Sunburg. 21 May 1981. REO 5610-5612. Mille Lacs Co: 5.8 km E Princeton. 25 May 1980. REO 5416. Morrison Co: 8.4 km W Pierz. 14 June 1981. REO 5676-5684. Sherburne Co: 6.7 km S Princeton. 25 May 1980. REO 5419. Stearns Co: 3.4 km W Paynesville. 14 June 1981. REO 5430. Swift Co; 27.8 km E Benson. 3 June 1980. REO 5427. Todd Co: 12.5 km E Osakis; 8.5 km E Long Prairie (voice records). R. E. Olson. Verified by R. E. Olson using voice records or karyotypes. There are no published records of this species in Minnesota. *Hyla chrysoscelis* occurs in the western, grassland counties, with no occurrence of *Hyla versicolor (sensu stricto)* documented west of central Stearns Co. Thus, strict allopatry of these species is demonstrated in the ecologically different areas approaching the grasslands: both species occur in forests, but only *Hyla chrysoscelis* in grasslands.

HYPEROLIUS ARGUS. AFRICA: TANZANIA: Tanga Region. Korogwe District. West Usambara Mts, Ambangulu tea estate, 5°05'S, 38°26'E, 12 km north of Korogwe, 1200 m asl. 23 February 1981. K. M. Howell and S. N. Stuart. Verified by Miss A. G. C. Grandison. British Museum (Natural History) (BM. 1982.565). Adult female collected from herbaceous vegetation 0.3 m above ground level, at edge of road near stream in intermediate altitude rain forest, canopy of which dominated by *Newtonia buchanaii.*

Schiotz (1975. The Treefrogs of Eastern Africa. Steenstrupia, Copenhagen) records this species from "coastal Kenya to Mozambique, in the lowlying eastern parts of the savanna." In Tanzania, it is known from Muheza, Ngomeni, and Amani (in and near the East Usambara Mts), Kilosa, and Morogoro, Dar es Salaam, the Mtwara area, Mafia and Zanzibar islands. This is the first record from the West Usambara Mts, 23 km W Amani and 220 km NE Morogoro.

Submitted by **K. M. HOWELL,** Department of Zoology and Marine Biology, Box 35064, University of Dar es Salaam, Dar es Salaam, Tanzania and **S. N. STUART,** Department of Applied Biology, University of Cambridge, Pembroke St., Cambridge, United Kingdom. ●

LEPTOPELIS VERMICULATUS. AFRICA: TANZANIA: Tanga Region. Lushoto District. West Usambara Mts, University of Dar es Salaam's Mazumbai Natural Forest Reserve, 4°48'S, 38°29'E, 8 mi NE Bumbuli, 1500 m asl. November 1980. S. N. Stuart. Verified by A. G. C. Grandison. British Museum (Natural History) (BM. 1982.582). Korogwe District. West Usambara Mts, Ambangulu Tea Estate, 5°05'S, 38°26'E, 12 km NW Korogwe, 1200 m asl. 20, 23 February 1981. K. M. Howell and S. N. Stuart. Verified by R. Crombie, U.S. National Museum of Natural History (USNM 226810), and A. G. C. Grandison, (BM. 1982.583, BM.1982.584-586). Previously known only from Amani in the East Usambara Mts (23 km due E Ambangulu and 34 km SE Mazumbai) and from Rungwe, ca. 750 km to the southwest (Schiotz. 1975. The Treefrogs of Eastern Africa. Steenstrupia, Copenhagen).

Submitted by **K. M. HOWELL,** Department of Zoology and Marine Biology, Box 35064, University of Dar es Salaam, Dar es Salaam, Tanzania and **S. N. STUART,** Department of Applied Biology, University of Cambridge, Pembroke St., Cambridge, United Kingdom. ●

CAUDATA

AMPHIUMA PHOLETER (One-toed Amphiuma). USA: ALABAMA: Baldwin Co: Fairhope, shore of Mobile Bay 0.4 km S of Fly Creek. 20 March 1984. S. D. Carey and D. M. Steedley. Verified by R. H. Mount. Auburn University Museum (AUM 32391). A cypress swamp, draining into Mobile Bay, is adjacent to the capture site and represents the only available habitat for *A. pholeter* in the immediate vicinity. Extends known range approximately 130 km to the west and is the first record for Alabama. (Mount. 1975. The Reptiles and Amphibians of Alabama. Alabama Agric. Exper. Sta., Auburn, AL; Means. 1977. Florida Mar. Res. Publ. No. 26:37-57).

TESTUDINES

ERETMOCHELYS IMBRICATA (Hawksbill). ST. HELENA ISLAND: (Southeast Atlantic Ocean), near Rupert's Bay, NW coast of island. 14 July 1983. Photographed at a depth of 10 m by A. Edwards. Museum of Comparative Zoology (Photo No. 797). The only other record for St. Helena is reported in a letter from A. Loveridge to L. Brongersma (Brongersma. 1982. Marine Turtles of the Eastern Atlantic Coast. In: K. Bjorndal (ed.) *Biology and Conservation of Sea Turtles.* Smithsonian Institution Press, Washington, D.C. pp. 407-416).

Submitted by **J. FRAZIER,** Department of Zoological Research, National Zoological Park, Smithsonian Institution, Washington, D.C. 20008, U.S.A. and **A. EDWARDS,** Department of Zoology, University of Newcastle upon Tyne NE1 7RU, England. ●

GRAPTEMYS VERSA (Texas Map Turtle). USA: TEXAS: McCulloch Co: 10 km SSE Brady on San Saba River at US Hwy 87. 15 March 1984. J. Bertl, T. James and F. C. Killebrew. Verified by F. C. Killebrew. West Texas State University Museum of Natural History (WTSU 9776). Previously recorded only in the Colorado River (Vogt. 1981. Cat. Amer. Amphib. Rept. 280.1-280.2). Extends range into a new drainage.

Submitted by **F. C. KILLEBREW, TERRY L. JAMES** and **JEFF BERTL,** Department of Biology, West Texas State University, Canyon, Texas 79016, U.S.A. ●

PELUSIOS NIGER (Black African Sideneck). AFRICA: LIBERIA: SINO: Sapo National Park, 22.5 km E Juazohn Village. 11 February 1983. E. Glumac, K. Kranz and J. Toah. Verified by R. Bour. Four color slides are deposited in the photographic file of the Division of Amphibians and Reptiles, USNM. The specimen was walking in several cm of water in a narrow creek draining into the Sino River. Sapo National Park is primarily composed of mature secondary evergreen forest (Voorhoeve, 1965 *Liberian High Forest Trees,* Wageningen.) Bour (1983, *Bull. Mus. Natn. Hist. Nat.* ser 4, 5A (1):343-382) could find one record from Liberia. Field work was funded by the Florida State Museum through a grant from the Griffis Foundation.

Submitted by **J. FRAZIER, K. KRANZ,** Department of Zoological Research, National Zoological Park, Smithsonian Institution, Washington, D.C. 20008, U.S.A.; **E. GLUMAC,** College of Agriculture, Texas A & I University, Campus Box 218, Kingsville, Texas 78363, U.S.A.; **J. TOAH,** Wildlife & National Parks, Forestry Development Authority, P.O. Box 3010, Monrovia, Liberia. ●

STERNOTHERUS ODORATUS (Stinkpot). USA: INDIANA: Wayne Co: 5.6 airline km SW Richmond. 13 June 1984. A. Whitman Miller and David P. Young, Jr. Verified by John B. Iverson. Joseph Moore Museum (HR-622). New county record fills hiatus between Henry County, IN (Minton, List and Lodato. 1983. Proc. Indiana Acad. Sci. pp. 489-498) and Darke County, OH (Conant. 1951. The Reptiles of Ohio, 2nd ed. Notre Dame, Ind.: American Midl. Natur.).

Submitted by **A. WHITMAN MILLER** and **DAVID P. YOUNG, JR.,** Biology Department and Joseph Moore Museum, Earlham College, Richmond, Indiana 47374, U.S.A. ●

SAURIA

ANOLIS SAGREI (Brown Anole). CAYMAN ISLANDS: GRAND CAYMAN: between Georgetown and South Sound. 20-26 February 1984. Twenty-two adults definitely identified by dewlap color. Voucher specimen in Minton Collection (No. 1899) from 1 km south of Georgetown. Collected 21 February 1984 by Madge and Sherman Minton. First record from Grand Cayman. Previously known from Little Cayman and Cayman Brac (Grant, C. 1940, Bull. Inst. Jamaica Sci. Ser. No. 2; Schwartz, A. and Thomas, R. 1975, A Checklist of West Indian Amphibians and Reptiles, Carnegie Mus. Nat. Hist. Spl. Pub. No. 1). In the immediate environs of Georgetown it appears to outnumber the endemic *Anolis conspersus;* between Georgetown and South Sound, *conspersus* outnumbers it in about a 2 to 1 ratio (based on sight records).

Submitted by **SHERMAN A. MINTON** and **MADGE R. MINTON.** Indiana University School of Medicine, Indianapolis, Indiana 46223, U.S.A. ●

ANOLIS SAGREI SAGREI (Brown Anole). USA: FLORIDA: Monroe Co: Dry Tortugas, Garden Key. Collected and verified by C. E. Winegarner, W. B. Robertson and W. Hoffman. 8-10 April 1983. Archbold Biological Station (ABS 921). 3 males, 1 female. First specimens from the Dry Tortugas. Nearest localities are Key West, 105 km east and northwestern Cuba, 170 km south. Specimens taken on a large pile of bricks and rubble just east of the moat surrounding Ft. Jefferson. Population currently seems limited to this small portion of the island so introduction may have been very recent. A construction barge moored adjacent to the collection site from October 1981 to June 1982, possibly was a source of colonizing individuals, however, the regular arrival of Park Service boats and private vessels are other possibilities.

Submitted by **CHESTER E. WINEGARNER,** Archbold Biological Station, Route 2, Box

180, Lake Placid, Florida 33582, **WILLIAM B. ROBERTSON, JR.,** South Florida Research Center, Everglades National Park, Homestead, Florida 33030, and **WAYNE HOFFMAN,** Biology Department, University of South Florida, Tampa, Florida 33620, U.S.A. ●

LYGOSOMA CF TANAE. AFRICA: TANZANIA: Kilimanjaro Region. Same District. South Pare, Ndungu Village, 4°20'S, 38°08'E, app. 500 m asl. January 1980. Collected by Ida Msechu. Verified by A. F. Stimson. British Museum (Natural History), (BM.1980.293). Found under leaf litter in banana plantation. Loveridge (1935. Bull. Mus. Comp. Zool. 59(1):11-12) collected the type and other specimens near the mouth of the Tana river in Kenya, and later (1957. Bull. Mus. Comp. Zool. 117 (2):214) gave the range for the species as "coastal Kenya" without listing further localities. This specimen, collected app. 345 km SW of the mouth of the Tana river, is the first record of the species in Tanzania.

Submitted by **K. M. HOWELL,** Box 35064, Department of Zoology and Marine Biology, University of Dar es Salaam, Dar es Salaam, Tanzania and **MS I. MSECHU,** Box 1622, Karatu Secondary School. Karatu, Tanzania. ●

TARENTOLA MAURITANICA (Moorish Gecko). GREECE: PELOPONNESE: Prefecture of Achaia: E border Patra city. 8 June 1971. Collected by D. Matopoulos and M. Kaparianos. Identified by B. P. Chondropoulos. Zoological Museum of Patra University (A-E 2402). The geographic distribution of *Tarentola mauritanica* in Greece is the Ionian islands Ithaki, Kefallonia and Zakynthos, as well as Crete (Ondrias. 1968. Liste des Amphibiens et des Reptiles de la Grèce. Biol. Gallo-Hellen., 1:111). This is the first record for the Peloponnese, indicating a larger range in Greece.

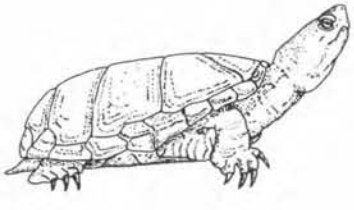
Submitted by **B. P. CHONDROPOULOS,** Section of Animal Biology, Department of Biology, Patra University, Patra, Greece. ●

SERPENTES

DRYMOBIUS RHOMBIFER. BOLIVIA: DEPT. DE LA PAZ: 20 km by river below Puerto Linares. 6 June 1981. Juvenile male (275 mm s-v) collected by T. S. Schulenberg. Louisiana State University Museum of Zoology (LSUMZ 43279). 29 June 1981. Adult male (841 mm s-v) collected by A. P. Capparella. LSUMZ 43278. Verified by D. A. Rossman. First specimens reported from Bolivia (Peters and Orejas-Miranda. 1970. Bull. U.S. Natl. Mus. 297, p. 99).

Submitted by **RANDY H. VAETH** and **DOUGLAS A. ROSSMAN,** Section of Herpetology, Museum of Zoology, Louisiana State University, Baton Rouge, Louisiana 70893, U.S.A. ●

LAMPROPELTIS CALLIGASTER CALLIGASTER (Prairie Kingsnake). USA: MISSOURI: Mississippi Co: 8 km S Charleston on Mo Rt 102. 28 April 1984. Michael A. Morris and Mary Beth Morris. Verified by M. A. Morris. Southern Illinois University at Carbondale (SIUC R-1797). Road-killed adult. Surrounding habitat grassy fields. First record for county and Missouri lowlands (Anderson. 1965. The reptiles of Missouri. Univ. Missouri Press, Columbia). Known from Jackson Purchase of Kentucky (Barbour. 1971. Amphibians and reptiles of Kentucky. Univ. Press of Kentucky, Lexington), but absent from Mississippi border of Illinois adjacent to Missouri lowlands (Smith. 1961. The amphibians and reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1-298). Helps fill gap in north-central part of range (Blaney, 1979, *Lampropeltis calligaster*. Cat. Amer. Amphib. Rept.:229.1-229.2).



Submitted by **MICHAEL A. MORRIS,** Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901 and **MARY BETH MORRIS,** 322 N. 9th Street, Murphysboro, Illinois 62966, U.S.A. ●

PITUOPHIS MELANOLEUCUS SAYI (Bullsnake). USA: TEXAS: Medina Co: 0.1 km W Castroville on US 90. 27 May 1984. C. T. McAllister and E. A. McAllister. Verified by R. Ward. North Texas State University Herpetological Collection (NTSUHC #R 655, head only). This represents a new county record filling a distributional hiatus between Bexar and Uvalde counties of southcentral Texas (Raun and Gehlbach. 1972. Amphibians and Reptiles in Texas. Dallas Mus. Nat. Hist. Bull. 2).

Submitted by **CHRIS T. McALLISTER,** Renal-Metabolic Lab (151-G), Veterans Administration Medical Center, Dallas, Texas 75216, U.S.A. ●

SONORA SEMIANNULATA (Ground Snake). USA: TEXAS: Kimble Co: 6.4 km N Jct. off US Hwy 83. 13 April 1984. C. T. McAllister and J. R. Glidewell. Verified by R. Ward. North Texas State University Herpetological Collection (NTSUHC R667-669). New county record and partially fills the distributional gap between Trans-Pecos and Edwards Plateau populations (Raun and Gehlbach. 1972. Amphibians and Reptiles in Texas. Dallas Mus. Nat. Hist. Bull. No. 2. These specimens were collected under limestone shelf rock in cedar glade habitat.

Submitted by **CHRIS T. McALLISTER,** Renal-Metabolic Lab (151-G), Veterans Administration Medical Center, Dallas, Texas 75216, U.S.A. ●

NEW DISTRIBUTIONAL RECORDS FOR SOME SEMIAQUATIC AMPHIBIANS AND REPTILES FROM THE RÍO SABINAS BASIN, COAHUILA, MEXICO

Milstead (1960) recognized 14 relict species inhabiting the Chihuahuan Desert, and identified the Rio Sabinas as an area with mesic-adapted relict species. Conant (1978) recognized 19 relict or riparian species from the Chihuahuan Desert, but omitted reference to several other semiaquatic forms that are apparently not restricted to riparian situations.

In May, 1983, we traversed the upper Río Sabinas drainage system, which until recently lacked adequate roads. Our collections include range extensions of relict and riparian species into the desert. These are marked below with an asterisk, and supplement localities recorded by Milstead (1960) and Conant (1978). Records of species he listed were verified by Conant (pers. comm.). Other data reflect new localities of semiaquatic species not restrictred to riparian habitats. Specimens are deposited in the Bobby Witcher Memorial Collection (BWMC) at Avila College, Kansas City, MO 64145.

SALIENTIA

BUFO PUNCTATUS (Red-spotted Toad): COAHUILA: 29 km N Musquiz (2 km N Puente El Corrizo) on Hwy 93. N. L. Laposha and J. S. Parmerlee. 28 May 1983. BWMC 2135.

BUFO SPECIOSUS (Texas Toad): COAHUILA: 43 km N Musquiz (16 km N Puente El Corrizo) on Hwy 93. D. D. Smith and R. Powell. 28 May 1983. BWMC 2136. 14 km N Musquiz (1 km S Puente Río Sabinas) on Hwy 93. N. A. Laposha and J. S. Parmerlee. 28 May 1983. Not catalogued, sent to the Direccion General de Flora y Fauna Silvestres, Mexico, D. F.

*BUFO VALLICEPS** (Gulf Coast Toad): COAHUILA: 37 km N Musquiz (10 km N Puente El Corrizo) on Hwy 93. R. Powell and D. D. Smith. 28 May 1983. BWMC 2134. 16 km N Musquiz (1 km N Puente Río Sabinas) on Hwy 93. N. A. Laposha and J. S. Parmerlee. 28 May 1983. Not catalogued, sent to the Direccion General de Flora y Fauna Silvestres, Mexico, D. F. Río Sabinas at San Juan de Sabinas. D. D. Smith. 27 May 1983. BWMC 2133.

RANA BERLANDIERI (Rio Grande Leopard Frog): COAHUILA: 10 km N Musquiz, Hwy 93. D. D. Smith and R. Powell. 28 May 1983. BWMC 2129. 7 km N Musquiz, Hwy 93. R. Powell and D. D. Smith. 28 May 1983. Uncatalogued specimen sent to the Direccion General de Flora y Fauna Silvestres, Mexico, D. F. Tadpoles, 27 km N Musquiz at Puente El Corrizo, Hwy 93, in pool of intermittent tributary stream. J. S. Parmerlee and R. Powell. 27 May 1983. BWMC 2148.

SCAPHIOPUS COUCHII (Couch's Spadefoot): COAHUILA: 34 km N Musquiz (6 km N Puente El Corrizo) on Hwy 93. N. A. Laposha and J. S. Parmerlee. 28 May 1983. BWMC 2131. 32 km N Musquiz (5 km N Puente El Corrizo) on Hwy 93. R. Powell and D. D. Smith. 28 May 1983. BWMC 2130.

TESTUDINES

KINOSTERNON FLAVESCENS (Yellow Mud Turtle): COAHUILA: 27 km N Musquiz at Puente El Corrizo, Hwy 93, in pool of intermittent tributary stream. J. S. Parmerlee, R. Powell, N. A. Laposha, and D. D. Smith. 28 May 1983. BWMC 2149, uncatalogued specimen sent to the Direccion General de Flora y Fauna Silvestre, Mexico, D. F.

*PSEUDEMYS CONCINNA** (River Cooter): COAHUILA: 27 km N Musquiz at Puente El Corrizo, Hwy 93, in pool of intermittent tributary stream. D. D. Smith, N. A. Laposha, R. Powell, and J. S. Parmerlee. 28 May 1983. BWMC 2087.

*TRIONYX SPINIFERUS** (Spiny Softshell): COAHUILA: 27 km N Musquiz at Puente El Corrizo, Hwy 93, in pool of intermittent tributary stream. N. A. Laposha, D. D. Smith, J. S. Parmerlee, and R. Powell. 28 May 1983. BWMC 2086, uncatalogued specimen sent to the Direccion General de Flora y Fauna Silvestres, Mexico, D. F.

BOOK REVIEWS

Amphibians and Reptiles of New England: Habitats and Natural History, by Richard M. DeGraff and Deborah D. Rudis. Illustrated by Abigail Rorer. University of Massachusetts Press, Amherst. 1983, 112 pp., 6 black-and-white photos, 56 drawings, 57 maps. $14.00 cloth, $6.95 paper.

In the first comprehensive survey of the New England herpetofauna in a very long time, the authors have undertaken the considerable task of synthesizing nearly 70 years of literature and documenting the distribution of 56 taxa. The book is intended for use by the scientific community, although it also will be interesting to amateurs.

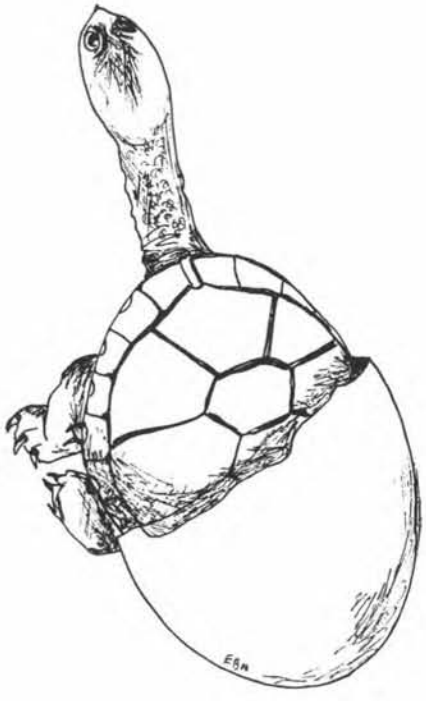
The text is introduced by sections on the history of herpetological investigations, habitats present, and population status of rare species. The species accounts that follow discuss abundance, habitat use, breeding biology, home range, and food. Accompanying maps illustrate general distributions and denote county records with dots. There is a wildlife management emphasis to much of the book, which reflects the conservation background of the authors. I find this orientation timely, particularly in light of the recent emphasis by many state agencies on nongame wildlife programs.

Despite this useful perspective, the book is weak in aspects of its systematic and ecological coverage. I feel that one of the principal functions of a regional work is to document morphological characteristics of local populations. Yet, no original measurements were made, and there is little discussion of regional color patterns. The weak patterning of northeastern *Scaphiopus holbrookii* compared to southern individuals should have been documented, for example. Moreover, descriptions of habitats sometimes emphasize vegetation features that are of questionable importance to reptiles and amphibians. The heavy reliance on personal communications tends to promote this incomplete view of habitat use, and it results in habitat specificity being implied when it is not really present. For example, it is unlikely that old fields are a "special" habitat requirement of *Terrapene carolina,* or that *Crotalus horridus* is restricted to forests with high rodent density. Rodent density undergoes dramatic temporal fluctuation, and in any event current *Crotalus* distribution is more closely tied to recent historical factors (e.g. eradication campaigns). Statements about the important role of herptiles in insect and rodent control (p. 10) also seem a bit sweeping, particularly considering recent studies that suggest resource superabundance in the northeast.

Concerning evolutionary topics, the discussion of speciation in Ambystomid salamanders is unfortunately worded to sound as if reproductive isolation was caused *by* glaciation rather than having developed *during* glaciation. Furthermore, hybridization between *Bufo americanus* and *B. woodhousii fowleri,* so frequent on Cape Cod and in coastal Connecticut, is not discussed at all. A recent MS thesis completed at the University of Connecticut provides additional data on intergradation between *Chrysemys p. picta* and *C. p. marginata.*

The distributional data presented, although by far the best in print, suffers from an incomplete review of collections. Several major New England collections, including those at the Yale Peabody Museum (YPM) and University of Connecticut (UCM), were apparently not examined. Notable omissions were those of Connecticut specimens of *Ambystoma tigrinum* (YPM) and *Trionyx spiniferus* (UCM). Some UCM leopard frogs also appear to be *Rana utricularia* rather than *pipiens.* In addition, Cope's classic *Batrachia of North America* (1889; U.S. Nat. Mus. Bull. 34), with its wealth of New England data, was not consulted.

I found most comments on abundance reasonable. However, the uncommonness of *Thamnophis sauritus* is overrated; it is regularly found in marshes. Recent discoveries of some large *Ambystoma* cf. *laterale* populations also suggest that members of the *jeffersonianum* complex may be more common than previously thought. Additionally, further discussion of the extent of the rarity of *Eumeces fasciatus* and *Scaphiopus holbrookii* would have been interesting. Many feel that both these species are well on the way to



extinction in New England. Finally, the tabular listing of *Desmognathus ochrophaeus* as rare in Connecticut (p. 8) is apparently a typographical error.

Even with the several shortcomings of the text, the authors are to be commended for their substantial compilation. They have summarized a great deal of regional literature and have included many original observations. Readers will find the comments section of the species accounts particularly enlightening. Individuals interested in the northeastern herpetofauna will find this a useful volume.

A Review of the Diseases and Treatments of Captive Turtles, by James B. Murphy and Joseph T. Collins, 56 pp. 1983. AMS Publishing, Lawrence, Kansas 66044.

This book, as the authors have stated, is useful primarily for those who deal with chelonians professionally, particularly veterinarians. But it should be found in the library of anyone who keeps turtles, as it is especially useful when consulting with a professional. The most valuable part of the book is the extensive bibliography after each chapter and at the end. The authors have done an exhaustive amount of work to bring together, in one volume, widely scattered information, consulting a variety of authorities, both with medical and non-medical backgrounds. Furthermore, the authors do a good job throughout the book of stating the findings of many researchers, yet reserving judgement about the "correct" procedure.

The preface must be read by all. The ethical statement made by the authors is important enough that I quote a part of it here. "The removal of a wild turtle from its natural environment, for whatever purpose, carries with it the ethical responsibility to house and maintain that turtle in a healthy state. Persons not wishing to shoulder that responsibility should not attempt to maintain captive turtles."

Although the contents may have been arranged in a number of ways, starting with "Environmental Factors" was a wise choice, since most problems are secondary to poor husbandry. Environmental factors, such as water temperature, light (quality and quantity), humidity and psychological requirements are listed and, for the most part, discussed adequately. Certain important points that the authors state include: matching the natural environment as closely as possible, minimum of 30-day quarantine of new arrivals, cleanliness of water, and availability of temperature gradients. One area that might have been stressed more in terms of importance was "Psychological Requirements." Many times this can be a cause of sudden illness in a long-term captive due to incompatibility during the mating season.

In the section, "Viral, Bacterial, Mycotic and Algal Infections," several good points are brought up. One stresses the importance of good hygiene of handlers so the handler doesn't get the disease. Another stresses increasing the temperature of the environment to help stimulate the immune system. Another states a very important fact: infections are often secondary to poor husbandry. Another important fact: know all about the drugs you are using - don't guess! Finally, the importance of a "culture and sensitivity" for identification and treatment of bacteria and fungi should have been better stressed by the authors. Although it may seem costly to the layman, it may prevent a delay in treatment without "guessing" which antibiotic will work, and perhaps prevent the loss of a valuable animal or animals.

In the sections, "Protozoan Infections," "Helminth Infections" and "Arthropod Infestations," it is emphasized that several fecal (stool) exams may be necessary to identify specific types of intestinal parasites so the correct "wormer" is used. This usually takes a professional. Another important point the authors stated is that one of the most effective ways of controlling parasite levels is through extreme cleanliness and sanitation. Furthermore, disinfectants must be carefully used, and those not recommended include ones containing coal tars, pine oils, carbolic acid, phenols, or heavy metals.

In the section "Dietary Deficiencies," it is stated that diet requirements (especially nutritional supplements) are still inadequately known. This is a big dilemma for any chelonian keeper, and no one diet has been proven successful for more than a few species; so the authors have listed an array of diets by many writers. In most cases, variety is the key. The authors recommended that no shellfish of any type be fed - but why?

In the section "Non-Infectious Diseases and Injuries" certain bacterial infections are mentioned, which may have been better included in a previous section. It does cover several medical problems, including cuts, shell repair, and nail and beak trims. Some can be handled by the layman, and some should be handled by professionals.

"Surgical Procedures" is definitely geared to the professional, especially the veterinarian, but can be understood by anyone with a biological background. Again, a good point is brought up by the authors: proper husbandry techniques will eliminate many surgeries. The radiology and electrocardiology segments might have been better placed under the previous section or a medical heading, but this is a minor point.

The "Necropsy Technique and Specimen Collection" section is again geared more for the professional, but it does bring up an important fact for the layman. A careful, thorough postmortem by a qualified pathologist familiar with reptilian tissues can be diagnostic for the dead — and the living. A very good detailed example is listed in this section.

The final section is the main bibliography. The bibliography itself, along with the sectional bibliographies, makes the book a valuable part of your library. This book would definitely make a nice gift for your veterinarian.

Iguanas of the World: Their Behavior, Ecology and Conservation, by Gordon M. Burghardt and A. Stanley Rand (eds.). 1982. Noyes Publications. 472 pp. $55.

Iguanines include a small but important group of lizards. Their large size, specialization for herbivory and adaptation to a diversity of ecosystems makes them ideal subjects for investigating a variety of interesting biological questions. Their attractive appearance, longevity, large size, palatability, and restriction of many to fragile habitats has led to heavy exploitation of them, both direct and indirect, by humans. Most, if not all, forms are threatened to some degree with extinction.

Burghardt and Rand have undertaken the ambitious task of organizing current knowledge on this group and focusing future investigation. Considering what was previously available, I suggest they have succeeded admirably. The general introduction and prologues to each of the six sections (Systematics and Biogeography, Food and Energetics, Demography and Life History Strategies, Adaptive Behavior and Communication, Social Organization, Conservation and Management) summarize the individual chapters well and crystalize the most important facts, hypotheses and approaches. The six topics reflect current interest and are logically arranged. The writing is well edited.

As in many symposium proceedings the contributions vary in breadth, readability and rigor of support of their conclusions. It is obvious from many contributions that only

Either stock or custom made.

Need Reptile, Amphibian & Specimen Identification Tags?

Order them here and now.

Stop your searching. Here are those identification tags you've been looking for. Save time, money and patience simply by ordering them right now from the NATIONAL TAG COMPANY. Use this page as your order form.

Non-soluble and waterproof inks • Special 10-pt. stock impervious to solvents • Alcohol and formalin proof • Pre-punched • Consecutively numbered* • Rolls of 2M • 1-week delivery • Custom tags take slightly longer but can be printed on both sides.

*Note: Stock tags are consecutively numbered, but the starting number will vary for each shipment. There's no printing on back side. Custom tags can get any numbering sequence desired, with or without prefix letters, plus printing on the back side (illustration above).

NATIONAL TAG COMPANY, 815 S. Brown School Rd., Vandalia, OH 45377

Journal of Morphology

A Wistar Institute Press Journal

Carl Gans, Editor

The **Journal of Morphology,** widely recognized as the foremost journal in its field, is the oldest journal in the United States devoted to the study of morphology. Published monthly, the **Journal** comprises original research articles in cytology, protozoology, embryology, and general morphology. Beyond providing an outlet for original research, the **Journal of Morphology** offers the reader a reflection of major trends in morphology.

Manuscripts for consideration should be submitted to: **Dr. Carl Gans**, Division of Biological Sciences, The University of Michigan, Ann Arbor, Michigan 48109.

Indexed by: Biological Abstracts • Chemical Abstracts • Current Contents/Life Sciences-Social Science Index • Excerpta Medica • Index Medicus • Institute of Scientific Information-Soviet Union.

ISSN 0362-2525

additional long-term, intensive research will more definitely focus the issues and answer the most important questions.

The section on Systematics and Biogeography includes two chapters, one by Etheridge and the other by Blanc. Readers of these two chapters will obtain a good grasp of the taxonomy and current hypotheses of the evolutionary history of the iguanines. Etheridge's checklist, in particular, should prove a valuable starting point for those developing an interest in the group.

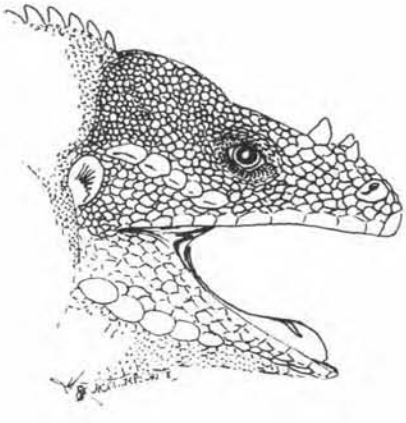
The section on Food and Energetics contains four chapters with rather different approaches that mesh well. Nagy presents a general model relating energy requirements to body size in iguanid lizards. It is based on studies of field metabolic rates of free living lizards (mostly insectivores) using doubly-labelled water techniques. He suggests how conservative this relationship seems to be and predicts what we should expect as data on energy requirements of more iguanas accumulate. Iverson offers a clear definition of herbivory, emphasizes the functional anatomy of iguanine herbivory, and discusses whether large size or herbivory evolved first. McBee and McBee document experimentally that hindgut fermentation produces volatile fatty acids that are a significant energy source to the green iguana. Auffenberg presents an extensively documented field study of feeding of the Caicos ground iguana, showing the complexity of factors to be considered in studying a foraging herbivore. He suggests that iguanas are highly selective feeders and not motivated solely by energy content as some simple foraging models suggest.

The section of Demography and Life History Strategy contains five chapters that point out variations in life-history traits among iguanas. Wiewandt summarizes variation among the iguanines in several life-history traits. He offers several speculative hypotheses for their evolution and he correctly points out that none but serious long-term efforts will succeed in significant advances in our knowledge. Rand and Green cleverly extract data from museum collections on geographic variations of the reproductive cycle of *Iguana iguana* and demonstrate a correlation of the reproductive cycle with the timing of the wet and dry seasons. Iguanas mate at the beginning of the dry season and hatching occurs at the beginning of the wet season. Thus, incubation occurs when it is appropriately dry and warm and hatchlings emerge to an abundant food supply of new leaves. Harris and Van Devender in separate chapters increase our knowledge of basic natural history of *Iguana* and *Ctenosaura* and demonstrate the difficulty involved in documenting iguanine demography. The growth rates of *Iguana* vary both geographically and seasonally. Van Devender speculates that herbivory may have preceded the evolution of large size in iguanas. Case presents the first detailed natural history account of the insular giant *Sauromalus*. Aside from large size the insular forms are unique in being very sedentary, showing an expanded niche, lacking aggression and having remarkably sporadic reproduction. In some years they are subject to devastating droughts during which reproduction ceases and mortality is high. Case presents a model invoking predation and starvation as cofactors in the evolution of large body size of these forms.

One of the special problems in constructing life-tables of the long-lived iguanines is the difficulty in accurately aging the oldest individuals. Several, e.g. Wiewandt p. 124, Dugan and Wiewandt p. 307, assume iguanas to have indeterminate growth that continues, albeit slowly, throughout life. If this is true, indirect data such as growth rings might be useful for determining absolute age; if not, such data can be seriously misleading (see Case p. 191). Only monitoring programs that follow marked individuals for perhaps decades will determine whether or not iguanine growth is truly indeterminate and reveal the true age structure of the populations.

The section on Adaptive Behavior and Communication seems random, which reflects the unfocused state of many aspects of the field of animal behavior. The first three chapters describe action patterns. Carpenter compares in his general qualitative style the aggressive displays of a diversity of iguanine species. Greenberg and Jenssen concentrate on the detail of displays of a small captive colony of *Brachylophus*. Distel and Veazey concentrate on an action pattern inventory of a captive group of *Iguana*. Each of the three are thoroughly descriptive but emphasize a different level of focus. The trio points out how hopelessly far we are from a complete understanding of display communication of any iguana species.

The last two chapters in the behavior section, one by Drummond and Burghardt the other by Boersma seem totally unrelated to each other or the previously described three chapters in this section. The first is an observational and experimental study of orientation and dispersal in hatchling *Iguana*. Hatchling iguanas do not disperse randomly but in the most advantageous direction; their choice of direction is influenced by their peers but other important environmental cues are obscure and probably complex. Boersma provides evidence for the hypothesis that Galapagos marine iguanas *(Amblyrhynchus)* form sleeping aggregations (cuddle) to retain heat for faster more efficient digestion. The aggregation seems to serve functionally like the burrow of the land iguanas.



The fifth section, Social Organization, contains five chapters. The first chapter by Dugan and Wiewandt and the last by Ryan are comparative and attempt to provide an evolutionary framework to explain variations in social organization. Dugan and Wiewandt present terms and models currently used by sociobiologists. They point out factors that may influence through natural selection the social organization of the iguanines. They emphasize the uniqueness of iguanine social organization among the iguanid lizards but most of the discussion details known or suspected determinates of iguanine social behavior in a rambling non-comparative fashion. A concise tabular presentation that compares similarities and differences between iguanines and other iguanids and includes possible differences in the selective environment would have been a useful addition to their chapter.

Ryan's chapter on variation of chuckwalla mating systems includes concise, testable models of how variations of the environment and the cost of territoriality can alter behavioral strategies that in turn influence social organization. It provides an excellent example of how to start an analysis of the evolution of social organization.

The three middle chapters of the fifth section are noncomparative descriptions of social behavior of three different iguana species. Differences in emphasis, focus and the detail presented make comparison of the chapters by the reader difficult. Dugan clearly relates age to differences in mating strategy among male *Iguana* and shows that males do not actively "control" females or their critical resources. Hers is the most quantitatively documented of the three chapters. Werner describes the seasonal ontogeny of male territories in *Conolophis subcristatus*, shows the importance of the male-constructed burrow during the breeding season and emphasizes the dynamics of the male-female interaction. Christian and Tracy emphasize the nesting dynamics of *Conolophis pallidus* and detail the variability of nest construction and defense behavior. All three chapters provide important baseline information for future study of these and other species.

The final section on conservation and management begins with an introduction and is followed by a chapter by Fitch, Henderson and Hillis. Together these two contributions clearly detail the status of Central American and Caribbean iguanas. Strikingly absent is a chapter on status and management of the Galapagos iguanas. Gibbons and Watkins provide a general account of the natural history and status of *Brachylophus* in the South Pacific. The epilogue, a plea for the iguana as a peace symbol by Burghardt is entertaining but perhaps might have been replaced with a statement of overview with more heuristic impact. The volume contains important material that should be read by anyone interested in research, conservation or management of iguanas. Hopefully, in a decade or two, a more sophisticated sequel will result as was spawned by Milstead's 1967 symposium on lizard ecology.

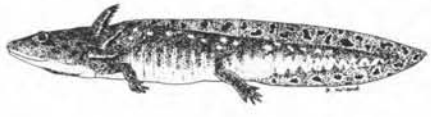
The Ecological Impact of Man on the South Florida Herpetofauna, by Larry Davis Wilson and Louis Porras 1983. The University of Kansas Museum of Natural History and World Wildlife Fund - U.S. $7.00 postpaid.

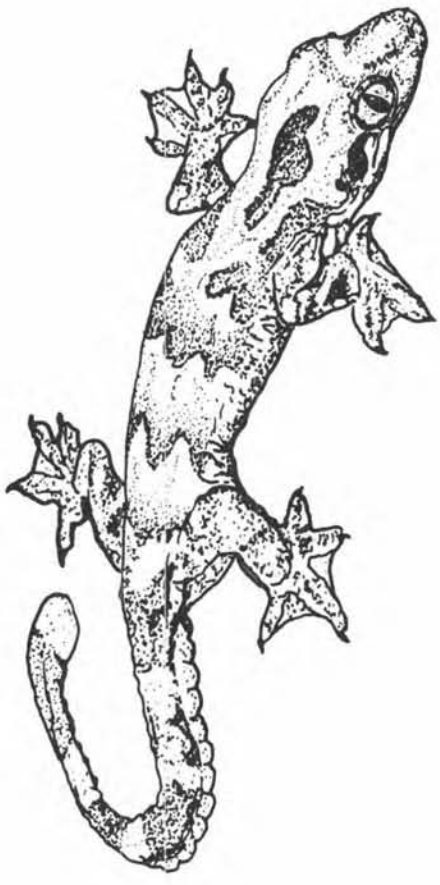
This book discusses the several intertwining environmental problems peculiar to southern peninsular Florida in a most lucid and readable manner. Consisting of 89 pages (+ i-vi) within which are discussed the environment, both historic and present, the severe and immediate problems created by a burgeoning human population and the status of the herpetofauna, native and introduced, it is a publication which should be of extreme interest to anyone with any affinity whatever to the "Sunshine State."

Besides being keen field biologists, the status of both authors in Florida (Wilson being an educator and Porras, until recently, being involved in the animal trade) has not only allowed them immediate access to reported introductions of alien reptiles and amphibians, but also given them the opportunity to critically evaluate such reports on both the short and long term basis.

While the introduction of herpetofauna has been reported in several prior publications, this is the first in several years to report on all known established introductions and to mention, at least cursorily, numerous failed introductions. It is, perhaps, the only booklet to explore the dramatic role played by the rampant environmental alterations which are occurring daily in Florida as they pertain to the herpetofauna. One may read of geologic, physiographic, hydrographic, climatic, vegetational and populational changes, the present as opposed to the historic, and gain insight and perspective while so doing.



The Florida as we knew it in the '50s, '60s, or even the '70s is a thing of the past. Unfortunately the environmental alterations have not lessened in the '80s. Indeed, the pressures of the never-ending flood of humanity have now grown to include most, if not all, of the counties south of a line connecting Tampa Bay, Gainesville and Jacksonville.



Where once existed wetlands now stand shopping malls; along the well drained central ridges so crucial to the existence of numerous threatened endemic poikilothermic creatures are citrus groves and mobile home parks of immense proportions.

While the "approaching ecocollapse" mentioned by the authors pertains specifically to southern Florida we will, I fear, see it echoed in more northerly areas of the state within the next decade or two.

In addition to the thought provoking text the book contains three maps or charts, five tables, 33 excellent quality black and white photographs, an extensive bibliography, appendix and an index to scientific names.

NEWSNOTES

NEW JERSEY STATE MUSEUM COLLECTION

The New Jersey State Museum has recently completed renovation of a new collection storage range for fishes, amphibians and reptiles. The ichthyological collection of The Wetlands Institute, made mainly by Lehigh University and Stockton State College, and the herpetological collection of the late James D. Anderson of Rutgers University have been donated to the museum and are now catalogued and incorporated into the museum's range. The collection is made up of more than 2,000 lots of fishes, amphibians and reptiles collected from across the State and its coastal waters during the 1950s, 1960s and 1970s. The amphibian collection is strong in series lots, particularly relating to specimens of *Ambystoma* adults and larvae, while the fish collection is strongest in bay and estuarine species. Computerization of the records of this collection will be undertaken this coming year. Persons interested in examining parts of this collection may do so by contacting:

Raymond J. Stein
Bureau of Science
New Jersey State Museum, CN-530
Trenton, New Jersey 08625, U.S.A. ●

NIXON GRIFFIS ESTABLISHES FUND FOR ZOOLOGICAL RESEARCH

New York Zoological Society trustee Nixon Griffis has established a unique fund for zoological research. Open to zoo and aquarium scientific staff members across the nation, fund recipients may be curators, keepers, veterinarians, and research and consulting biologists. Programs to be considered for support include those in: animal behavior, veterinary medicine, reproductive biology, genetics, exhibition design and other research areas that address the care, management and propagation of wildlife in captivity.

Grants, not to exceed $3000, will be awarded biannually. For information about the Fund and grant applications, interested biologists are urged to write to:

The Nixon Griffis Fund
for Zoological Research
c/o New York Zoological Society
185th Street and Southern Blvd.
Bronx, New York 10460, U.S.A. ●

HERP SLIDES REQUESTED

The Nevada Chapter of The Wildlife Society is nearing completion of a slide-tape program entitled *Silver Amphibians and Reptiles*. This conservation education tool will be available for free presentations and sale to the public in 1985. A few more slides are needed to complete the program. High quality color slides, horizontally oriented, depicting the animals and their habitats are being sought. Slides need not have been taken in Nevada but must be representative of the Silver State. All original slides will be returned to the owners. Photographers whose slides are selected for the program will be acknowledged in the written narrative. Specific slides needed are: bullfrog eggs, desert tortoise, rattlesnake combat dance, northwestern pond turtle. Please contact:

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

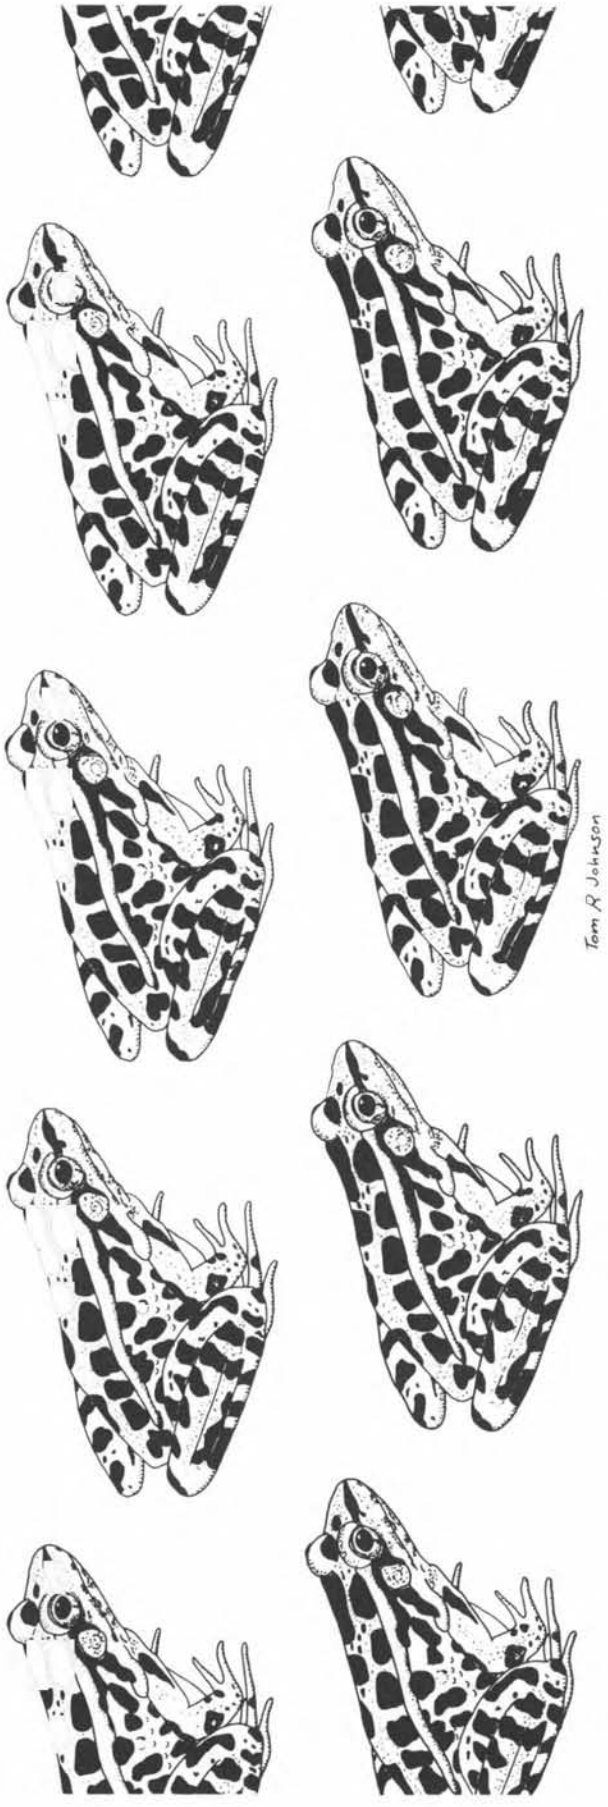
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), occasional issues of **Facsimile Reprints in Herpetology,** and **Recent Herpetological Literature.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1984

Student member	$17.00*
Regular member	$22.00*
Sustaining member	$35.00
Contributing member	$50.00
Institutional	$40.00

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).



*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

DUES INCREASE

The Board of Directors has approved an increase in dues for Sustaining Members to $35 per year. This increase is currently in effect. ●

1985 ANNUAL MEETING

The 1985 annual meeting will take place at The University of South Florida in Tampa, 4-9 August. Additional information about this meeting will be published in forthcoming issues of *HR*. Inquiries may be directed to:

Henry R. Mushinsky
Department of Biology
University of South Florida
Tampa, Florida 33620, U.S.A. ●

1984 CONSERVATION DIRECTORY

The 1984 SSAR Directory of State Nongame/Natural Heritage Program Coordinators, prepared by the SSAR Conservation Committee, is now available. This directory includes the names of state wildlife agency or commission employees who are responsible for nongame, significant habitat, or natural heritage programs and who have been designated as contacts on issues concerning threats to herpetofaunal resources. The 1984 edition is a thorough update of the 1983 version. Copies of the directory may be obtained gratis from:

John L. Behler
Department of Herpetology
New York Zoological Society
185th Street & Southern Blvd.
Bronx, New York 10460, U.S.A. ●

CORRECTION FOR IHIC ADDRESS

The address given for the Israel Herpetological Information Center (IHIC) in SSAR's Silver Anniversary Membership Directory (Herpetological Circular No. 13) is incorrect. The correct address for IHIC is:

Israel Herpetological Information Center
Mr. Amos Bouskila
Har Gilo
D. N. Harei Yerushalaim 91076
Israel

The IHIC is an enterprise of the Society for the Protection of Nature in Israel, in collaboration with Tel Aviv University and the Hebrew University of Jerusalem. It cooperates with both universities but is independent of them.

Please make the above address correction on p. 34 of your Directory. ●

8th ANNUAL REGIONAL HERPETOLOGICAL SOCIETIES CONFERENCE

The Eighth Annual Conference of the Regional Herpetological Societies will be held on the afternoon of Monday, 30 July 1984 with the combined meeting of SSAR-HL-ASIH at the University of Oklahoma at Norman. The title of the conference is: "Monitoring Reptile and Amphibian Populations: An Important Role for Regional Herpetological Societies." The program will include the following presentations:

Mike Plummer (Harding University, Searcy, Arkansas) will present techniques used to study reptile populations with an emphasis on turtles.

Ray Semlitsch (Savannah River Ecology Laboratories, Aiken, South Carolina) will discuss techniques he has used in research on amphibian populations.

Steven Secor (University of Oklahoma, Norman) will discuss DOKARRS, a computer program that stores distributional and other information on collections and site records of reptiles and amphibians as well as museum records. These data are then used to plot up-to-date distribution maps and other information on range, reproduction-status, population structure, etc.

Steve Hammack (Fort Worth Museum of Science and History and the North Texas Herpetological Society) will report how their regional society, with the aid of a grant from the SSAR, has compiled distributional data for a publication and slide presentation on the "Reptiles and Amphibians of Dallas and Taron Counties, Texas."

Additional information on the conference may be obtained from Jeff Black, Department of Biology, Oklahoma Baptist University, Shawnee, Oklahoma 74801, U.S.A.

For information on the combined meeting of SSAR-HL-ASIH contact the local chairman: Victor Hutchison, Department of Zoology, University of Oklahoma, Norman, Oklahoma 73109, U.S.A. (405)-325-6721. ●

NEW SUBSECTION IN *HR*

Herpetological Review is adding a new subsection to its Geographic Distribution section. It will be called "Recent Population Changes" and will provide a widely disseminated outlet for anecdotal or minimally documented information on local extinctions or regional population changes.

RATIONALE: Very little information about fluctuating population sizes or of local extinctions ever reaches the research literature. When such things happen, local investigators usually are not aware of anything having happened until after the fact (often several years) and thus there has been little or no data accumulation for formal scientific substantiation. By ignoring such information, however, the scientific community is being deprived of valuable historic indications that might enhance our understanding of very long term population trends (in excess of 20 years) and changes in distribution patterns. *Herpetological Review* can provide that informational outlet because it imposes fewer strictures on material that can be published.

If you feel you have a suitable contribution for the new subsection, please inform its Editor (Dr. Ralph W. Axtell, Department of Biological Sciences, Southern Illinois University, Edwardsville, Illinois 62026, U.S.A.) of your interest or provide a preliminary manuscript for his attention. ●

SYMPOSIUM ON PREDATOR-PREY RELATIONS IN LOWER VERTEBRATES

This symposium will critically examine the value and contribution of diverse approaches to the study of predation and predator defense. Participants are specialists in the physiology, morphology, ecology, and behavior of predator-prey relationships, and include A. Bennett, I. Johnston, P. Webb, G. Roth, C. Gans, M. Feder, G. Lauder, R. Huey, G. Helfman, E. Werner, J. Endler, and S. Arnold. Participants will examine questions such as: What are the advantages and drawbacks of particular types of analyses (e.g., experimental, comparative, ecological, natural historical) in understanding predator-prey relationships? What major questions in each area are yet to be answered? How can diverse approaches be integrated? Contributed papers will follow the symposium sessions. The symposium is supported in part by the National Science Foundation and is organized by M. Feder and G. Lauder. It will be held on July 31-August 1, 1984, at a combined meeting of the American Society of Ichthyologists and Herpetologists, Herpetologists' League, and Society for the Study of Amphibians and Reptiles, in Norman, Oklahoma. For information contact Dr. Victor Hutchison, Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019, U.S.A. ●

SOCIETIES

Celebrating its 10th year, members of the Kansas Herpetological Society gathered in Lawrence, Kansas for their annual meeting in November 1983. The Society plays an active role in herpetological and conservation activities in Kansas. With over 200 members worldwide, the KHS publishes a quarterly *Newsletter* and other publications on an occasional basis, the most recent a color brochure on endangered and threatened amphibians and reptiles in Kansas, co-sponsored by an SSAR Grant-in-Herpetology. Photo by Joseph T. Collins. ●

MEETINGS

CAPTIVE PROPAGATION AND HUSBANDRY SYMPOSIUM

The Eighth International Herpetological Symposium (formerly Reptile Symposium) on Captive Propagation and Husbandry will be held 17-21 July 1984 in Columbus, Ohio, hosted by the Columbus Zoo. In addition to papers on herpetological husbandry and propagation, there will be a tour of the College of Veterinary Medicine, Ohio State University, including demonstrations of the latest diagnostic veterinary techniques, and an open house at the Columbus Zoo Reptile and Amphibian facilities. For registration information contact:

Herpetological Symposium
13019 Catoctin Furnace Road
Thurmont, Maryland 21788, U.S.A. ●

CAPTIVE PROPAGATION CONFERENCE

The Northern California Herpetological Society will sponsor its second conference on the Captive Propagation and Husbandry of Reptiles and Amphibians on January 19 and 20, 1985 in Davis, California. All herpetologists, either amateur or professional, are invited to attend and/or present a paper at the conference.

The Proceedings of the 1983 conference are available at $13 per copy.

Abstracts for the 1985 meeting (due by August 30, 1984) or requests for the 1983 Proceedings should be sent to:

Randall L. Gray
NCHS
706 Arnold Street
Davis, California 95616, U.S.A. ●

THIRD INTERNATIONAL CONGRESS OF SYSTEMATIC AND EVOLUTIONARY BIOLOGY, 1985

The Congress will be held on 4-10 July 1985 at the University of Sussex, near Brighton, England. It is sponsored by the Royal Society, British Ecological Society, Linnean Society, Palaeontological Association and Systematics Association.

The major aims of this Congress are to encourage and facilitate the integration of the work of biologists in adjacent or overlapping fields in the general area of systematic and evolutionary biology.

The programme will include a number of symposia devoted to specially-selected broad interdisciplinary themes, with invited speakers. The proposed subjects include: Symbiosis in Evolution; Conservation of Tropical Ecosystems; Biogeographic Evolution of the Malay Archipelago; Adaptation Aspects of Physiological Processes; Co-evolution in Ecosystems and the Red Queen Hypothesis; Angiosperm Origins and the Biological Consequences; The Measurement of Rates of Evolution; Molecular Biology and Evolutionary Theory; Co-Evolution and Systematics; Molecules vs. Morphology in Phylogeny: Conflict or Compromise? Random and Directed Events in Evolution; Biochemical Innovation in Microbial Communities.

There will also be a full provision for intending participants to suggest and arrange symposia of special interest to particular groupings of biologists. Other sessions will provide opportunities for the presentation of papers concerned with particular topics or groups of organisms. There will also be a number of poster sessions.

Accommodation and meals will be available on the campus of the University of Sussex. In addition, hotels are available in nearby Brighton, an attractive historic resort town on the South Coast.

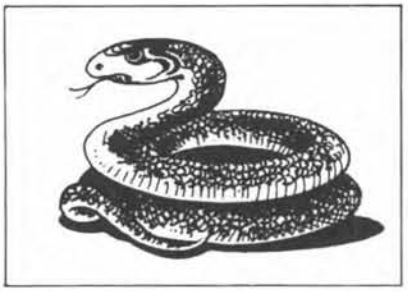
Further information will only be sent to those who request it. Anyone wishing to be placed on the mailing list, or to suggest topics for Special Interest Symposia, or to contribute to any of the Congress Symposia listed above, should write to:

Professor Barry Cox
c/o ICSEB Congress Office
130 Queen's Road
Brighton, Sussex BN1 3WE, U.K. ●

SECOND INTERNATIONAL COLLOQUIUM ON THE PATHOLOGY OF REPTILES AND AMPHIBIANS

The Second International Colloquium on the Pathology of Reptiles and Amphibians will take place in Nottingham, England, 17-21 September 1984. The scientific sessions will be held at the Medical School of the University of Nottingham, part of the Queen's Medical Centre, which opened in 1976.

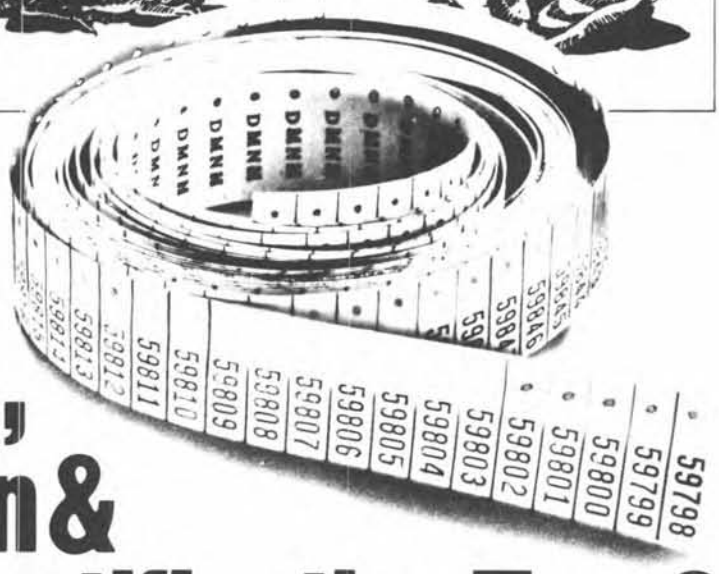
Sessions on the following topics are being planned: Immune responses and immunopathology; spontaneous tumours and chemical carcinogenesis; microbial and parasitic diseases; developmental abnormalities and mutations; problems related to maintenance in captivity.



Further information may be obtained from:

Dr. Richard Clothier
Department of Human Morphology
University of Nottingham Medical School
Nottingham NG7 2UH, England ●

CHEMICAL SIGNALS IN VERTEBRATES IV



The Fourth International Conference on Chemical Signals in Vertebrates, formerly held in Sarasota, Florida and Syracuse, New York, will be held at the University of Wyoming, Laramie, from 27-29 (and the morning of the 30th, if necessary) July 1985. Paper and poster presentations will be by invitation only, and the International Organizing Committee requests input, inquiries, and correspondence from those who wish to present a topic or simply attend. The meeting will take an evolutionary, ecological, and comparative theme, but in this context specific presentations will likely consider issues as wide ranging as pheromone chemistry, endocrine and neurobiological mechanisms, matters of adaptation and preadaptation, life history ecology and strategy, ethology, and general evolutionary and comparative biology. Proceedings of the meeting will be published as Chemical Signals in Vertebrates, Vol. 4. For further information, contact:

Dr. David Duvall, Chair
International Organizing Committee
Chemical Signals in Vertebrates IV
Department of Zoology and Physiology
University of Wyoming
Laramie, Wyoming 82071, U.S.A. ●

IN MEMORIAM

It is with great sorrow that the herpetological community learned of the recent death of Dr. T. Paul Maslin, Curator-Emeritus of the University of Colorado Museum and Professor of Biology. Dr. Maslin passed away on Sunday, 26 February 1984.

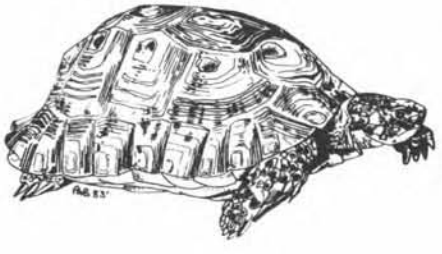
After receiving his Ph.D. from Stanford in 1945, Dr. Maslin began his academic career at Colorado State University. He moved to the University of Colorado two years later where he served as professor of Natural History and curator of zoological collections until his retirement in 1973. During this period he dedicated his life to teaching and to the building of the Museum's herpetological collections. He earned an international reputation for his discovery in 1961 that the whiptail lizard *Cnemidophorus* is an all-female species.

We offer our condolences to Dr. Maslin's wife Mary, daughter Diana, and three grandchildren Shona, Aaron and Zacharias Baum. ●

LEGISLATIVE ALERT

The U.S. Fish and Wildlife Service has taken the following actions: the Hierro giant lizard *(Gallotia simonyi simonyi)* is now an endangered species and the Ibiza wall lizard *(Podarcis pityusensis)* is a threatened species, under the provisions of the Endangered Species Act of 1973, as amended. In addition, the Service delisted the Indian flap-shelled turtle *(Lissemys punctata punctata)* from provisions of the Act. This rule became effective on 30 March 1984. Refer to the Federal Register, Vol. 49, No. 41, Wednesday, 29 February 1984. ●

A presidential decree from the President of Greece, published in January 1981, proclaims ten species of amphibians and thirty-nine species of reptiles, as well as numerous other plants and animals, as being protected species for which collecting, wounding, killing, preserving, buying, selling, transporting and exporting from Greece is prohibited without permission from the Ministry of Agriculture and notification of the Biological Department of a Greek University. Additional species of animals may have been added to the list since the initial decree. The Hellenic Zoological Society is willing to offer any information to those interested in Greek fauna and is soliciting input concerning the biological status of the Greek fauna as it relates to the need for protection of species. For further information contact:



Dr. S. Drosopoulos, Secretary
Hellenic Zoological Society
P.O. Box 3249 C.T.
Athens 102 10, Greece ●

NEWSNOTES

Varanus INFORMATION SOUGHT

Current plans call for completion of my long-term studies of *Varanus bengalensis* under both captive and wild conditions within the next two years. My intention is to produce a volume on this species similar to that on *V. komodoensis*. My interest in making this new piece as complete as possible suggests that I call on the herpetological community for help in documenting as much regarding the biology of this species as possible. Accordingly, I would be pleased to consider for inclusion in this volume (with due credit given, of course) those items you consider of possible importance that might corroborate, refute, or extend published information. Please contact:

Walter Auffenberg
Florida State Museum
University of Florida
Gainesville, Florida 32611, U.S.A. ●

SEXUALLY DIMORPHIC PLASTRAL KINESIS IN *Heosemys spinosa*

A plastral hinge is not currently considered to be characteristic of the batagurine turtle genus *Heosemys* (McDowell, 1964). Bramble (1974) predicted that plastral kinesis would be found in the genus when he included *Heosemys* in the *Cyclemys* group of genera. My observation of a distinct functional hinge in two live adult female *H. spinosa* which I collected in Malaysia confirms Bramble's prediction.

Plastral kinesis in *H. spinosa* has probably not been reported previously because there is no indication of a hinge in adult males or juveniles and the kinesis of females is poorly developed. Externally, the hinge is indicated by incomplete separation of the abdominal scute into hyoplastral and hypoplastral elements and by fragmentation of the inguinal scute (Fig. 1). Modification of the inguinal scute into small plates separated by expandable sulci permits dorsal-ventral movement of the hypoplastron. Internally, the hinge mechanism consists simply of a pad of fibrous connective tissue separating the hypoplastral buttress from the carapace (Fig. 2). Maximum ventral displacement of the plastron of the freshly-sacrificed specimens was only about 3.5 mm, measured at the tip of the anal scute. In adult males and juveniles there is a rigid suture connecting the immobile plastral and carapacial bones.

The plastral kinesis of *H. spinosa* does not appear to provide any protection to the turtle. Perhaps the limited movement of the plastron allows the production of larger eggs than would otherwise be possible. That hypothesis is consistent with the well-established trend for tropical birds and turtles to lay larger eggs than temperate species (MacArther, 1962). Between the time of capture and 15 months later when the females were sacrificed no change in the hinge mechanism was noticeable. It is certainly possible, how-

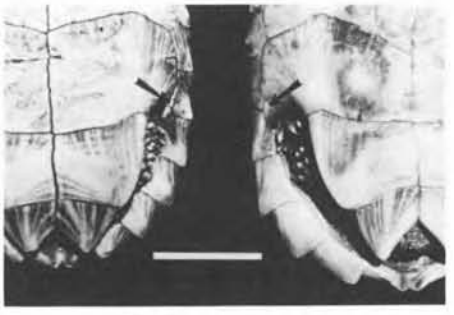


Figure 1. Plastron of adult male (right, UU 17299) and female (left, UU 17313) *Heosemys spinosa*; arrows point to an inguinal scute of the male and a homologous structure of the female. Incomplete separation of the abdominal scute of the female is visible on the specimen illustrated, the inguinal and abdominal scutes of a second female (UU 17314) are similar to those of the specimen figured. Scale = 50 mm.

Figure 2. Anterior aspect of left hypoplastral buttress of a freshly-sacrificed female *Heosemys spinosa* (UU 17313). The arrow indicates the pad of connective tissue on the dorsal extremity of the buttress. Scale = 10 mm.

ever, that prior to egg-laying the hinge complex could be enhanced by bone resorption and substantially increase the small amount of kinesis observed.

The male shown in Figure 1, and the female shown in Figures 1 and 2, and the second female turtle referred to in this paper have been deposited with J. M. Legler, curator of the Museum of Zoology (Herpetology), University of Utah, and they have been catalogued as numbers UU 17299 and 17313-17314.

NATURAL LONGEVITY OF IGUANID LIZARDS IN SOUTHERN NEVADA

Maximal life spans of animals have long held a general interest for biologists. Indeed, Major Stanley Flower, a British fusilier, occupied himself for years in cataloging ages of animals kept as pets or in zoos for long periods of time (e.g., Flower, 1937). More recent records of captive longevities have been summarized by Bowler (1977). The problem with observations of this nature is that records of animals in captivity have no clear relevance to natural situations.

Very aged animals in natural populations are of little functional significance. Even if these individuals remain sexually active, they contribute only a tiny fraction to overall reproductive effort. However, life spans may be selectively influenced, and knowledge of this attribute can be of value in comparing different populations of the same species. Information drawn from protracted field studies of long-lived species is of particular interest.

Table 1. Observed life spans among four species of iguanid lizards in Rock Valley, Nye County, Nevada.

Species	Sex	Estimated age (months) at conclusion of study	Estimated age (months) when first registered (and snout-vent length, mm)
Cnemidophorus tigris	m	94	10 (67)
	m	94	12 (--)
	f	81	22 (78)
	f	81	22 (84)
Crotaphytus wislizenii	m	118	8 (84)
	m	117	33 (100)
	f	82	2 (68)
Phrynosoma platyrhinos	f	82	10 (72)
	f	82	22 (81)
	m	81	22 (78)
	m	81	0 (35)
	m	81	1 (34)
Uta stansburiana	f	58	7 (38)
	f	46	19 (48)
	f	45	13 (48)
	m	45	22 (54)
	m	37	8 (45)

Field studies of lizards were carried out in Rock Valley, Nye County, Nevada (Turner et al., 1969a, b, 1970; Medica et al., 1973; Turner, 1977). Work was conducted in four 9-ha areas, three of which were fenced. One of the fenced areas was continuously irradiated during the course of these investigations. Sampling occurred regularly between early March and September, 1962-1973. Ages of all lizards were estimated at time of first capture, basing these estimates on the animals' sizes. At the beginning of the study, ages of many individuals of longer-lived species *(Phrynosoma platyrhinos, Cnemidophorus tigris, Crotaphytus wislizenii)* could not be accurately determined, and this was also true of a few of the largest *Uta stansburiana*. However, as the study progressed new animals encountered were generally new recruits of readily ascertained age. Ultimately, as the older lizards disappeared, we worked with populations of known age distributions. All field procedures were described by Medica et al. (1971).

Although we have records from all four areas, we restricted our analysis to two fenced plots, excluding the irradiated area and the unfenced area. Sterility of some female lizards inhabiting the irradiated area was described previously: *Crotophytus* and *Cnemidophorus* (Turner et al., 1973); *Phrynosoma* (Medica et al., 1973); and *Uta* (Turner and Medica, 1977; Pearson et al.) Table 1 gives longevity data for the oldest individuals observed among four species of iguanids. Ten of the 17 lizards were originally marked within their first years of life, and only one was assigned an age exceeding 22 months at time of first capture.

These observations indicate natural life spans of about 94 months in *Cnemidophorus*, 118 months in *Crotaphytus*, 82 months in *Phrynosoma* and 58 months in *Uta*. Female *Uta* definitely outlive males, as we suggested in an earlier analysis (Turner et al., 1969c) and as observed by Tinkle (1967) in Texas. We believe that the observed longevities of *Uta* represent the true capacities of this species in southern Nevada. On the other hand, had observations been continued we probably would have observed longer life spans among some individuals of the other three species.

The figures in Table 1 can be given added interest by considering the number of different lizards registered in the two plots between 1962 and 1973. The numbers of each species (with numbers of males and females in parentheses) were as follows: *Uta stansburiana* 3,575 (1,753:1,822), *Cnemidophorus tigris* 1,097 (532:565), *Crotaphytus wislizenii* 202 (109:93), and *Phrynosoma platyrhinos* 249 (140:109). Chi-square tests of observed sex ratios gave X^2 values (1 d.f.) of around 1 to 1.7 for *Uta*, *Cnemidophorus* and *Crotaphytus* and 3.6 for *Phrynosoma*. All are statistically insignificant ($X^2 0.05 = 3.8$), assuming an expected sex ratio of 1:1.

ACKNOWLEDGMENTS

We thank the many people who assisted with the field work in Rock Valley between 1962 and 1973, particularly, Gerard A. Hoddenbach and Joseph R. Lannom, Jr. We acknowledge the support of the Civil Effects Test Operations office at the Nevada Test Site. This work was supported by Contract DE-AM03-76-SF00012 between the U.S. Department of Energy and the University of California and by the International Biological Program/Desert Biome (National Science Foundation Grant BG32139).

MORPHOLOGICAL CHARACTERISTICS OF A PERIPHERAL ISOLATE OF THE PARTHENOGENETIC TEIID LIZARD, *Cnemidophorus flagellicaudus*

On 7 July 1983, we unexpectedly encountered an individual of *Cnemidophorus flagellicaudus* at the site of Clay Springs Ranch, approximately 25 air miles (40 km) NNW Hackberry, Mojave Co., Arizona (35° 43' 42" N—113° 52' W). Eleven specimens were collected between 3:00 and 6:30 P.M. (MST), and seven more were secured on the morning of 8 July (numbers HLT 8337-54). The sample was collected within an elevational range of 4280 to 4400 ft. (1305 to 1342 m) from a "weed habitat," as defined by Wright and Lowe (1968).

The site lies at the bottom of a box canyon that ascends from the Hualapai Valley in a NE direction to penetrate the Grand Wash Cliffs. An unimproved road parallels a narrow wash at the bottom of the canyon. The margins of this wash are dominated by mesquite *(Prosopis juliflora)* and catclaw *(Acacia greggi)* trees. The five large specimens (86-93 mm SVL) were collected from this association. Tree density diminishes on the adjacent gentle, gravelly slopes, and there are many small clearings dominated by snakeweed *(Gutierrezia sarothrae)*, annual grasses, and scattered *Opuntia* and *Cholla* cacti. Eleven of twelve smaller specimens (64-75 mm SVL) were collected from such clearings. This apparent ecological segregation may be seasonally based because of differences in the reproductive physiology of the two size classes (see Table 1). Upper slopes of the canyon are dominated by blackbrush *(Coleogyne ramosissima)* and include occasional juniper outliers from the woodland that occupies the plateau above. One or more springs emanate from the northwest slope. The presence of water has stimulated past human efforts to capture and divert this resource for human and livestock needs, and this activity has resulted in a locally disturbed habitat. *C. flagellicaudus* was the only species of the genus found at this site, although *C. tigris* was locally abundant at lower elevations in the contiguous Hualapai Valley.

Table 1. Reproductive data from the Clay Springs sample of *Cnemidophorus flagellicaudus*.

The Clay Springs sample provides important information related to this species:

1. The range for *C. flagellicaudus* is extended approximately 71 miles NW of the northern boundary previously described (Lowe and Wright, 1964) and mapped (Wright and Lowe, 1968; Behler and King, 1979).

2. The maximum body length is at least 93 mm, exceeding the previously reported maximum by 5 mm (Lowe and Wright, 1964).

3. The ranges of variation for four other taxonomic characters (GAB, FP, PV/GAB x 100, and IPS) are extended beyond values previously reported (Lowe and Wright, 1964).

4. An opportunity is provided for describing the ontogenetically transient color pattern of young adult individuals.

Statistical Comparisons. Data reductions for our sample are summarized in Table 2 along with those for previously reported *C. flagellicaudus* and *C. sonorae* samples. Character abbreviations used are:

GAB = number of dorsal granules around midbody. This count was standardized as per Wright (1966).

FP = number of femoral pores.

PV = number of dorsal granules separating paravertebral stripes.

PV/GAB x 100 = an average ratio of PV to GAB, expressed as a %.

IPS = ratio of interparietal scale width to length, expressed as a %. Measurements were made with an ocular micrometer and dissection microscope. Means for IPS for individuals >85mm (N=5) and for individuals <86 mm (N=11) were 72.7 and 73.3 respectively. Because of this close agreement, all individuals were treated as a single sample.

SVL = Snout-vent (body) length measured to the nearest mm with dial calipers.

Lowe and Wright (1964) alluded to intraspecific variation occurring within this species. This fact is illustrated in Table 2. The intraspecific differences in FP and GAB means for the two *flagellicaudus* samples are greater than the interspecific differences in FP and GAB between *C. flagellicaudus*[1] and the two samples of the superficially similar *C. sonorae*.

Color Pattern. Lowe and Wright (1964) described the color patterns of hatchlings and large adults of *C. flagellicaudus*, but the transient color pattern of individuals in the ontogenetic shift from unspotted hatchlings to spotted adults has not been reported. The following description refers to the color pattern, in life, of individuals 64-75 mm in SVL. A comparison is made with the color pattern characterizing the larger individuals (> 85 mm SVL) of our sample (see Figure 1).

Table 2. A comparison of quantitative characters of the Clay Springs sample of *Cnemidophorus flagellicaudus* with published values for other samples of this species and for *C. sonorae*. Data sequence is mean and (one standard error), (range of variation), and sample size. See text for abbreviations.

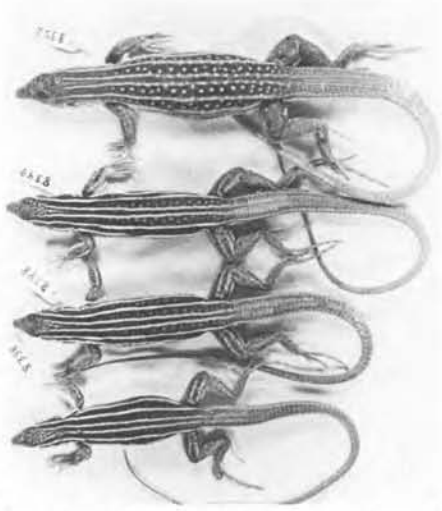

Figure 1. Dorsal view of representatives of *Cnemidophorus flagellicaudus*. Body lengths (SVL) from bottom-to-top are, respectively: 64, 74, 75, and 93 mm.

There are six stripes, and some individuals have a partial vertebral stripe on the nape. The stripes are pale yellow on the sides of the head and nape. The paravertebral stripes lose the yellow pigment and become light tan posteriorly; the dorsolaterals fade to white. The lateral stripes are white for their entire length, exclusive of the neck area. The paravertebral stripes have slightly irregular margins; the other stripe margins are straight, and all stripes are sharply defined. Middorsal, dorsolateral, and lateral darkfields are very dark brown. The flank darkfields are paler and a gray-brown shade. Indistinct, pale brown spots appear in the dorsolateral and lateral fields by the time a body length of 64 mm has been attained, but the middorsal and flank fields remain essentially unspotted throughout pattern ontogeny. Enhancement of pale spot definition begins at a body length of about 75 mm. The spots become relatively smaller, lighten to a pale tan shade, develop sharply defined margins, and contrast sharply with fields and stripes. This change occurs in a posterior-to-anterior direction. A further increase in body size is accompanied by reduction of stripe definition and the superimposition of pale spots on them. The stripes on the nape become pale chartreuse. Middorsal, dorsolateral, and lateral darkfields lighten to a medium brown shade, and the tail color changes from completely light brown to pale blue-green distally. The dorsal surface of each thigh is light gray-brown, with two irregular, tan stripes. The shank is gray-brown and mottled. These surfaces are uniformly pale brown in large individuals. The forearms have a dark brown dorsal surface, each bearing, posteriorly, a single longitudinal, pale brown stripe. This surface lightens in ontogeny, and the forearm stripe is not visible in large individuals. The ventral surface of all age groups is white and immaculate.

ACKNOWLEDGMENTS

We thank Hobart M. Smith and J. Martin Walker, respectively, for information regarding distribution literature and reproductive analysis. Field work was made possible by funding by Regis College, Department of Biology. Various aspects of the study were facilitated by a Regis College Faculty Development Grant awarded to the senior author.

In 1867, four renegades founded a journal.

Of the four men who left the Museum of Comparative Zoology in Cambridge to found **The American Naturalist,** two also participated in the founding, sixteen years later, of the American Society of Naturalists. The Society and the journal have worked closely together ever since, furthering the advancement and diffusion of knowledge about organic evolution and other broad biological principles.

In 1983, AN is still at the forefront.

One of the oldest scientific periodicals in the United States, **The American Naturalist** is also one of the foremost publications in the world for research in ecology, evolution, and population biology. Drawing upon examinations of all biotic kingdoms, the **Naturalist** emphasizes sophisticated analyses, innovative theoretical syntheses, and empirical discoveries with broad general implications.

A round table on research in ecology and evolutionary biology

This November 1983 special issue — which features contributions by J. Roughgarden, J. Quinn and A. Dunham, C. Toft and P. Shea, D. Simberloff, D. Strong, J. Connell, and G. Salt — is scheduled to become a book in Spring 1984.

PROPOSAL FOR A PHOTOGRAPHIC METHOD FOR SIZE ESTIMATES OF CROCODILIANS

Recently, Magnusson (1983) summarized the advantages and disadvantages of visual estimates of size of crocodilians. His experiments showed that inexperienced observers could not accurately estimate the lengths of pieces of cord whose sizes were comparable to those of crocodilian heads under field conditions. However, he did conclude that experienced observers are able to use a series of clues that enable fairly accurate size estimates to be made with some species.

If an observer can get close enough to a crocodilian to make a visual estimate of the length of a crocodilian's head, then they are close enough to take a photograph. An electronic flash at night does not appear to disturb wild crocodilians and a photograph of the head often gives definitive taxonomic data and features that may be measured accurately.

In four species examined for this report, increasing size is associated with a progressive lengthening of the snout in relation to the total head length (Fig. 1). *Crocodylus intermedius* measured were captive specimens, whereas the others were wild caught.

Given that the ratio of the snout length divided by the total head length of any one species is related directly to the total size of the individual, then a photograph of a crocodilian head (when taken at right angles to the head) can be used to calculate this ratio, and thus the size of an individual. Since it is a ratio, it is a figure that is somewhat independent of the distance at which the photograph was taken.

Preliminary results show that providing the photograph is taken at right angles to the head of the animal, then the ratio calculated from a 35mm colour slide projected onto a screen is the same as the ratio obtained by direct measurement. Deviations from 90° will distort the ratio measured on a photograph, but since an observer is invariably higher than the crocodilian head to be photographed,

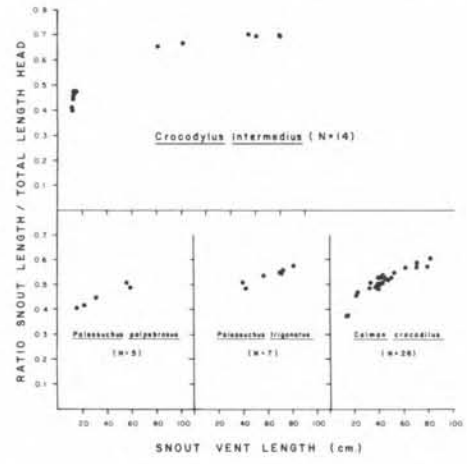

Figure 1. The Snout Length:Total Head Length Ratio as a function of the snout-vent length in four species of crocodilians.

and can thus usually see both of the eyes, the eye orbits may be used in the manner of rifle sights to orientate the observer to the required angle. When both eye orbits of the crocodilian are in line with the eye of the observer the head of the crocodilian is at a 90° angle, and therefore at the correct angle to be photographed. Adult crocodilians will often facilitate this by swimming broadside on to the observer. Failing this many individuals stay on the surface long enough for an observer, either on foot or in a boat, to move their position.

I have not attempted to fit curves to Fig. 1 because the data are incomplete, and ratios derived from photographs need to be compared with those derived from direct measurements. It can be seen from Fig. 1 that the ratio levels out when a snout-vent length of about 80 cm is reached. Thus, this technique has limited use for the adults of large species. These few data did not show any obvious differences between sexes of any one species. Webb and Messel (1978) have shown sexual dimorphism in *Crocodylus porosus* with regard to interocular width and the width of the head at the midpoint of the cranial platform, and Ayarzagüena (1980) has demonstrated that the eyes of female *Caiman crocodilus* are proportionally larger and more rounded than in the male. It may well be possible to detect such differences with photographs. I am initiating such a study, and am most interested in pooling my data with other crocodilian workers to see if calibration curves for the aforementioned species can be derived.

EGG EXTRUSION AFTER BELLY PRESSING: A SIMPLE MEANS FOR THE DETERMINATION OF OVULATION IN THE SMOOTH NEWT

In a number of urodele amphibian species, females do not ovulate unless they have been inseminated (Humphrey, 1977; Tsutsui, 1931). In the roughskin newt *Taricha granulosa*, ovulation appears to be induced via a neuroendocrine reflex involving male courtship behavior, insemination and the hormone progesterone (Moore, McCormack and Swanson, 1979). This mechanism of induced ovulation can be seen as an adaptation that prevents the wastage of female parental effort resulting from oogenesis and premature ovulation in the absence of active spermatozoa.

During the course of an investigation of the breeding ecology of the smooth newt, *Triturus vulgaris*, a simple method was discovered which enables one to determine whether females have started to ovulate and, thus, have probably mated.

METHODS AND RESULTS

If a female smooth newt is held belly upwards and gentle pressure is exerted by rolling a finger along the belly in a snout-vent direction, up to 3 eggs, encapsulated in jelly coats, may be extruded from the cloaca. These eggs appear to be identical to those which females normally lay, wrapped individually in the leaves of aquatic plants.

Three experiments were conducted to determine if extruded eggs are indeed ovulated and fertilized eggs.

1. Fifty extruded eggs were collected from 21 females in the field. These eggs were brought back to the laboratory and maintained in plastic troughs containing aged tap water. Within 3 to 4 days, developing embryos were clearly visible in 37 (74%) eggs. None of these developed as far as hatching, due to a fungal infection.
2. Five females which extruded eggs in the field were maintained in the laboratory in individual troughs containing aged tap water and pieces of aquatic vegetation. Within 7 days, all of the females had laid eggs, and inspection of the clutches revealed them to contain developing embryos.
3. Female newts captured on land as they migrated to the water (N = 5) and captured in the water (N = 14) had their bellies pressed and were then preserved in formalin. Upon dissection, a check was made for the presence of eggs in the oviducts. None of the females captured on land extruded eggs when pressed and none contained oviducal eggs. This result is not surprising, as smooth newts court and oviposit in water. Seven of the aquatic females extruded eggs when pressed, all of them also containing oviducal eggs. Of the 7 aquatic females which did not extrude eggs, only 2 had eggs in their oviducts.

DISCUSSION

The data presented above strongly suggest that extruded eggs are fertilized and that egg extrusion after belly pressing is a reliable indicator of ovulation in the smooth newt. Failure to elicit egg extrusion usually, but not always, indicates the absence of ovulation. Such failure may result if a female has either not been inseminated, or if she has already laid her complement of yolked eggs.

The technique of belly pressing has obvious application for the field biologist requiring a simple, quick and reliable means for assessing the reproductive status of a female. It is currently being used to determine the proportion of a population of female smooth newts which are available for mating at any given time in the breeding season. Knowing this proportion, it is then possible to calculate the operational sex ratio of the population (see Emlen and Oring, 1977), for inseminated females tend to be unresponsive to further

male courtship (Halliday and Verrell, in press). The usefulness of belly pressing in other urodele species is currently under investigation; preliminary results indicate that female crested newts (*T. cristatus*) and palmate newts (*T. helveticus*) will extrude eggs if their bellies are pressed.

I thank Verina Waights for her assistance in conducting the experiments and Tim Halliday for reviewing the manuscript. Financial support was provided by the Open University Research Committee.

NATURE PRINTS
BY DAVID M. DENNIS

We are pleased to offer four exquisite, full-color art prints by David M. Dennis, naturalist and professional scientific illustrator renown for his watercolors of unusual wildlife.

Plate 1: *Green Frog and Damselfly*
Plate 2: *Painted Turtle and Dragonfly*
Plate 3: *Spotted Salamanders in Courtship*
Plate 4: *Red Salamander and Hercules Beetle*

Prints measure 20 x 24 inches (51 x 61 cm), each signed and numbered by Mr. Dennis in editions limited to only 500 copies. $30 each or $95 for set of four prints plus shipping ($4.50) and any New York taxes.

AMPHIBIAN AND REPTILE BIOLOGY AT CORNELL UNIVERSITY

Cornell University has had a long tradition of research and training in herpetology, beginning most prominently with the work of Albert Hazen Wright, a member of the zoology faculty from 1908 to 1947. Wright had many distinguished students—among them Sherman C. Bishop, Raymond B. Cowles, James Kezer, Ch'eng-chao Liu and Karl P. Schmidt—and gained prominence from his studies on the life histories of frogs of the Ithaca area and those of the Okefenokee Swamp and from his handbooks of frogs and of snakes, both co-authored with his wife Anna. Indeed, it was largely through the Cornell expeditions to the Okefenokee from 1909 to 1922 by Wright and his students (including Bishop, W. D. Funkhouser and Francis Harper) and their extensive publications on the fauna and flora of this great swamp on the Georgia-Florida border that it was eventually set aside as a national wildlife refuge (in 1937). Wright was one of the pioneers in ecology, as recognized in 1955 by his election as Eminent Ecologist by the Ecological Society of America.

Earlier, Simon Henry Gage, who retired in 1908, conducted studies of respiration in turtles and amphibians but is also known for having worked out in detail the complex life cycle of the red-spotted newt (published in 1891). Gage co-founded Comstock Publishing Company in 1893, and later donated it to Cornell University Press. The well-known handbooks of American frogs (by the Wrights, published 1933), salamanders (by Bishop, 1943), lizards (by Hobart M. Smith, 1946), turtles (by Archie Carr, 1952), and snakes (by the Wrights, 1957) were issued under the Comstock imprint. Benjamin F. Kingsbury, Gage's successor, published extensive studies on amphibian anatomy including the gut, lateral line system, brain and the columella auris. Later still, Howard B. Adelmann, who had been an associate of Hans Spemann at Freiburg, conducted a long series of experimental studies on development of the eye, lens and mesoderm in salamanders.

Today, studies in herpetology at Cornell are no less active but are more widely dispersed in several academic units as a result of the reorganization of biology and the establishment of an intercollegiate Division of Biological Sciences in 1964. All of the biology units are located on the central campus, including the Sections of Ecology & Systematics and Neurobiology & Behavior which occupied two new research buildings there in 1982. We take this opportunity, therefore, to provide a brief review of current activities, including those of recent graduates.

RESEARCH

In the Department of Anatomy of the College of Veterinary Medicine Daniel Blackburn, a student of Howard E. Evans, is completing his Ph.D. dissertation on the evolution of viviparity and fetal nutritional specializations in reptiles and other vertebrates. Blackburn analyzed the selection pressures, preadaptations, and constraints affecting reproductive mode evolution. He also compared placentation and reproductive anatomy of some representative reptiles, including *Mabuya heathi*, a species that has evolved a suite of "eutherian" reproductive specializations. Earlier, Blackburn completed a masters thesis under Harvey Pough, on the comparative, functional, and evolutionary myology of sceloporine iguanid lizards. Howard Evans, who has published extensively on the anatomy of fishes, snakes and birds, has completed a revision of his chapter on reptile anatomy in "Zoo and Wild Animal Medicine," to be published shortly by W. B. Saunders Co.; included in the revision are illustrations and descriptions of the pelvic limbs and cloacal region of pythons. In the Department of Physiology of the same college Charles L. Guard is studying reptilian digestive physiology and recently completed a major review of the subject that was published by Cambridge University Press.

In the Section of Genetics and Development of the Division of Biological Sciences, several individuals in the laboratory of Antonie W. Blackler are studying gene regulation in *Xenopus* frogs. Blackler is engaged in a study of the control of rRNA synthesis at an abbreviated rRNA locus translocated to the end of a chromosome that does not normally carry it, and with Robin Tropper is engaged in a study

of nucleolar fusion in cells that carry the translocation in single and double copies. Sharon Camhi is using the fluorescent property of *X. borealis* chromosomes to examine the effects of cytoplasmic aging prior to fertilization. Michael Newstein is determining the gene copy number in the *X. laevis* translocation, and whether the translocated locus is active during oocyte gene amplification. Other projects in Blackler's lab concern allelic exclusion at the "*albino*" locus in *borealis*/*laevis* hybrids and determination of the distribution of sex-determining loci in the *Xenopus* genome.

In the Section of Ecology & Systematics, Harvey Pough's research interests center on ecological energetics. He is continuing work on simultaneous changes in physiology, morphology, and behavior during the post-metamorphic ontogeny of anurans. Suzanne Kamel, after completing a master's degree with Robert Gatten at the University of North Carolina at Greensboro, spent the summer of 1983 at Cornell working with Pough in these studies. Kamel has now begun doctoral study with Martin Feder at the University of Chicago. Robin Andrews, from Virginia Polytechnic Institute and State University, is spending her sabbatical leave as a Visiting Professor at Cornell in 1984. Pough and Andrews are engaged in studies of lizard energetics, especially the energy costs of feeding. Gatten and also Kirk Miller of Franklin and Marshall College will spend portions of their sabbaticals in Pough's lab in 1984-85. Pough and Margaret M. Stewart from SUNY at Albany, and their students, have collaborated since 1979 in a study of the Puerto Rican coquí, *Eleutherodactylus coqui*. Among other results, they have found that the density of populations of coquíes in the forest at El Verde depends upon the availability of daytime retreat sites. The coquíes have complex water-conserving behaviors they employ during their nightly periods of activity. Frogs that are prevented from exerting this behavioral control over evaporative water loss may become lethally dehydrated during a night, whereas free-ranging frogs experience negligible water loss. The frogs' hydroregulatory behaviors interact with other activities like feeding and calling in a manner analogous to the thermoregulatory behavior of lizards. Coquíes have been shown to have internal fertilization, and the eggs are brooded by the male. Predation by other male coquíes is a major source of egg mortality, and a brooding male defends his eggs against these incursions. The attending male also provides water to the eggs, which triple their mass during development. Eggs that do not absorb sufficient water during development are unable to use all the yolk, and produce smaller than normal hatchlings. Alan de Queiroz is a new graduate student in Pough's laboratory. His interests center on behavioral ecology, and he has been attempting to quantify aspects of prey-handling behavior of snakes and lizards.

Theodore Taigen completed a doctorate in Pough's lab in 1981 with a series of studies of the relationship between exercise physiology and behavior of anurans. In collaboration with Pough and with Sharon Emerson from the Field Museum of Natural History, Taigen found a close correlation between aerobic capacity for exercise and the foraging mode used by a phylogenetically and ecologically diverse group of anurans. Subsequently, in collaboration with Pough, he extended these analyses to field studies of time budgets of frogs in Panama and Puerto Rico. Taigen is now an assistant professor at the University of Connecticut. In conjunction with Kentwood Wells, who obtained his doctorate in Pough's lab in 1976, Taigen has begun measurements of the energetic cost of anuran vocalizations. Carol Beuchat finished her doctorate in Pough's laboratory in 1982 with a study of the ecological and physiological consequences of viviparity for *Sceloporus jarrovi*. She found that pregnant female lizards thermoregulated at lower body temperatures than males or post-parturient females. Pregnant female lizards had higher metabolic rates than non-pregnant lizards, and oxygen consumption during parturition increased to four to six times resting values. In conjunction with Steven Ellner, a graduate student in applied math at Cornell, Beuchat developed a general model for the costs and benefits of thermoregulatory behavior. Currently Beuchat is continuing postdoctoral work with Eldon Braun and David Vleck at the University of Arizona. Ellen and Robert Dawley will join Ecology & Systematics next fall, sharing the position of instructor in "The Vertebrates" course. Ellen is finishing her doctorate with Wells studying olfactory communication in salamanders.

The Cornell Laboratory for Ecological and Evolutionary Genetics, housed at Langmuir Laboratory, is engaged in electrophoretic studies of evolution by gene duplication of polyploid fish, amphibians and other organisms. Ellen Marsden, a student of Peter Brussard, is working with the tetraploid *Hyla versicolor* and its diploid counterpart *H. chrysoscelis* as well as species from the polyploid lineage *Xenopus*.

Alan H. Savitzky taught at Cornell from 1978 to 1982, both for Ecology & Systematics and for Neurobiology & Behavior, and was for several years in charge of the laboratories for "The Vertebrates" course. Savitzky, now assistant professor of biology at Old Dominion University in Virginia, is continuing his studies of snake functional morphology and systematics. In particular, he is studying the parallel evolution of specialized feeding and defensive structures, including venom delivery systems and morphological correlates of aquatic foraging.

In the Section of Neurobiology & Behavior there are several students and faculty working with amphibians and reptiles. Joanne Ballarino, a student of Howard C. Howland, is studying the formation of otoconial crystals in the otolithic organs of vertebrates. Reptiles are the key phylogenetic group in this comparative study since they produce both aragonite and calcite crystals, typical of amphibians and of birds and mammals, respectively. Leo J. Fleishman, another of Howland's students, is studying visual communication in *Anolis* lizards. His particular interest is perception of motion, how they discriminate important (e.g., prey, predators, displays of conspecifics) from less relevant motion such as windblown vegetation. Fleishman's field work is done at the Smithsonian Tropical Research Institute in Panama. Paul Watson, a student of Stephen T. Emlen and Paul W. Sherman, is investigating the reproductive biology of the newt. In particular, he is studying the fall reproductive period, especially the significance of male pheromones for intersexual selection and coordination of mating. He is presently attempting to purify and chemically characterize the pheromones.

Students in the laboratory of Robert R. Capranica are studying various aspects of communication in frogs. Harold Zakon completed a dissertation on the anatomy and electrophysiology of regeneration of the eighth cranial nerve in *Bufo* and *Rana*. After transection, the auditory nerve fibers regenerate with a remarkable precision to reestablish their exact same synaptic terminals in the central auditory system. Walter Wilczynski, a postdoctoral fellow in Capranica's laboratory, completed anatomical and electrophysiological studies on sound localization in anurans. He discovered that sound reaches the inner ear in two ways (via the tympanum and also a separate extratympanic route) that interact to permit directional sensitivity. Both Zakon and Wilczynski are now assistant professors of zoology at the University of Texas at Austin. David Yager, a current student, is conducting studies of sound production and communication in *Xenopus*. He found that the larynx comprises about one-quarter of their body size and that their mating calls are produced by an unique mechanism involving "implosion" in the larynx. Presently he is studying call discrimination among hybrids and their parental species. Gary Rose, now on a postdoctoral at University of California, San Diego, completed a dissertation on temporal processing in the auditory system of frogs, in particular the way in which amplitude-modulated (AM) calls are transformed when being passed from peripheral to central auditory systems. The central neurons are tuned to preferred rates of AM in a species-specific way. Andrea Megela, now assistant professor of biology at Brown University, performed electrophysiological and behavioral studies of species of *Rana* and *Hyla* in which adaptation rates of auditory nerve fibers range from phasic "on" units to tonic patterns. The results suggest that rapidly adapting fibers play an important role in sound localization. Robert Capranica is currently involved in a project on accuracy of female phonotaxis and their ability to discriminate the male calls against a complex acoustic background. Field studies are being conducted in South Africa with *Hyperolius* and *Kassina*, and his electrophysiological studies in the laboratory deal with neural encoding of frequency-modulated (FM) calls in the peripheral and central auditory systems. Two-choice female phonotaxis trials verify that the direction, rate and frequency range of modulation are critical cues in species recognition.

Also in the Section of Neurobiology & Behavior, students in Kraig Adler's group are studying various aspects of orientation behavior, sensory physiology and social behavior. Michael J. Ryan completed his thesis on sexual selection and communication in the neotropical frog *Physalaemus pustulosus;* the thesis will soon be published in book form by University of Chicago Press. Ryan found

that the call components serve different functions: the "whine" is involved in species recognition while the "chuck" provides information used in mate choice by females, who choose the largest males by discriminating the fundamental frequencies of the chuck component. At the Smithsonian station in Panama, he has also worked collaboratively with A. Stanley Rand on *Physalaemus* biology and with Merlin D. Tuttle on the frog-eating bat *Trachops*. Ryan is presently a Miller Fellow at University of California, Berkeley, and in September will become assistant professor of zoology at the University of Texas, Austin. Gordon H. Rodda finished a dissertation on orientation and navigation in alligators, research in which he used resighting, radiotracking and arena-testing techniques. Juveniles homed accurately, with no evidence for random searching, although habitat barriers deflected their homeward paths. Older juveniles tested in distant arenas were highly oriented toward home and errors in their headings were correlated to natural variation in the dip angle of the earth's magnetic field; significantly, the errors were correlated with magnetic values only within 20 min. of testing time, suggesting that dip angle may provide one component of an hypothesized bicoordinate map sense. Rodda just completed a Smithsonian postdoctoral project in Venezuela on iguana social behavior and is now assistant professor of psychology at University of Tennessee. Bruce Waldman, presently a postdoctoral fellow at Cambridge University, finished a dissertation on kin recognition and sibling association in anurans. He found that *Bufo americanus* tadpoles chose to associate with siblings, preferring full-siblings over paternal, but not maternal half-siblings. Recognition was not dependent upon prior experience with siblings since the preference occurred even when embryos were allowed to hatch in isolation, but early postembryonic interactions can alter their recognition template. Comparative studies on *Rana sylvatica* tadpoles also revealed sibling preferences but other aspects were significantly different. In September 1984 Waldman will join Harvard University as assistant professor of biology.

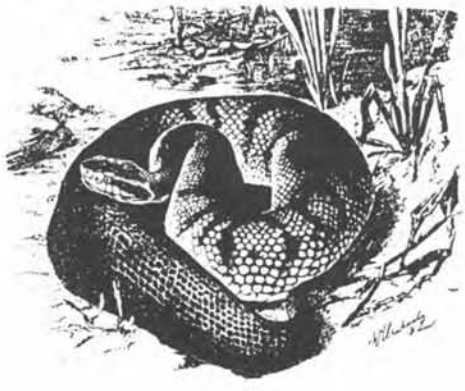
Among Adler's current students and associates, John B. Phillips is studying the ability of newts to use magnetic cues for orientation and navigation. Phillips has shown that magnetic cues can be used as a compass and is currently determining whether newts have an axial or polar compass mechanism. In other studies, partly in collaboration with Adler, Phillips is investigating the possibility that newts, which are unusually sensitive to the earth's magnetic field, may utilize magnetic cues also as a map, studies involving both correlational analyses and direct experimental tests. In Fall 1984 Phillips will begin a postdoctoral fellowship in neurophysiology at Yale University to study sensory aspects of orientation. John D. Crawford is presently studying the use of skylight polarization cues for orientation, both in frogs and lizards. He is researching the role of the lizard parietal eye as a polarization analyzer, using single-unit electrophysiological techniques. In addition, he is examining the importance of individuality in frog orientation. Douglas Brust, an undergraduate honors student working under Adler's supervision, is finishing a study of thermoregulatory behavior in iguanas, a field study begun in Venezuela in 1982. Brust will begin his doctoral work with Vleck at the University of Arizona next fall. Robert Madden, professor at Marymount College in Tarrytown, New York, regularly comes to Cornell each summer to conduct his on-going studies of orientation in *Chrysemys picta*. He has developed a simple test arena, one that can be easily transported to critical sites and in which the turtles exhibit consistent orientation. Kraig Adler is exploring several aspects of the orientation behavior of amphibians and reptiles. Recently he completed a study, using a portable apparatus that shifts the magnetic field, showing that newts do not monitor the magnetic field during displacement; the complementary experiments are now underway to test for the use of magnetic cues only at the time of release. Another of his projects involves the use of polarization cues by the desert lizard *Uma notata*. He has shown that they can orient to polarized light patterns and do so in a time-compensated manner; currently he is studying the possible role of the parietal eye as the critical analyzer. A list of available reprints of papers by the Adler group can be obtained on request.

TEACHING

An introductory course, "The Vertebrates," forms the basis of the undergraduate curriculum in vertebrate biology. The textbook *Vertebrate Life* by William McFarland, Harvey Pough, Tom Cade and John Heiser had its origin in that course. After "The Vertebrates," undergraduates can take courses in mammalogy, ornithology, ichthyology, or herpetology. The "Herpetology" course, offered in the fall term in alternate years, is taught by Harvey Pough and enrolls about 25 students. Extensive teaching collections, housed in Stimson Hall, are used for the vertebrate biology courses, and Ithaca's location in the Finger Lakes region of upstate New York allows field trips to a variety of habitats near campus.

Reptiles are being treated in increasing numbers at the Small Animal Clinic of the Veterinary College, and interest in reptile and amphibian medicine continues to grow among Cornell's veterinary students. For each of the past few years, the student chapter of the American Association of Zoo Veterinarians has organized a herpetological seminar series on taxonomy, captive raising, and clinical methods. In recognition of the expanding need for professionals with expertise in the area, the American Veterinary Medical Association will soon recognize Zoo Animal Medicine as a certified board specialty.

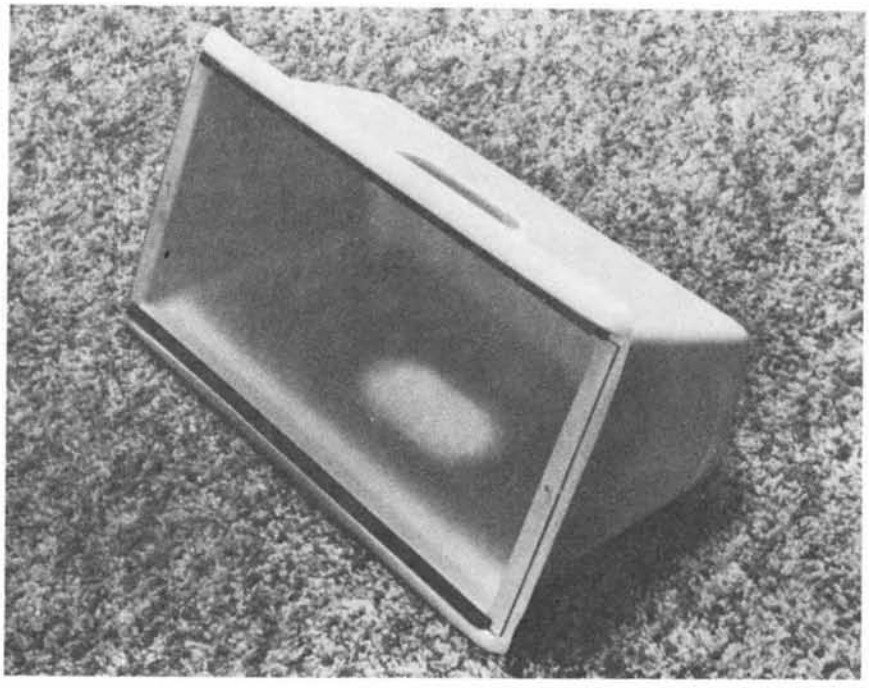
There is also an active student zoology club, "Jordani," that sponsors a monthly lecture and film series, field trips and other programs. The club is named for David Starr Jordan, the famed ichthyologist who occasionally published in herpetology and authored the *Manual of the Vertebrates*, mainstay of vertebrate biology courses in America for several decades at the turn of the century. Jordan graduated from Cornell in 1872, the only person in the university's history to receive a masters degree upon completion of an undergraduate course of study!



COLLECTIONS

The Vertebrate Collections are administered by the Section of Ecology & Systematics. The fish collection is largest, with about 1,000,000 specimens; the bird and mammal collections total about 53,000 specimens. The herpetology collection, with a total 30,000 specimens, was organized by A. H. Wright; the first catalog entry is dated January 10, 1922. Wright's specimens from the eastern United States, particularly from the Okefenokee Swamp, comprised the majority of the initial holdings. During his term as curator, Harvey Pough added 6,000 specimens, concentrating on material from outside North America. As a result of his efforts, there are significant holdings from Costa Rica, Puerto Rico, and Australia. Requests for loans should be addressed to the present curator, Amy R. McCune at the Section of Ecology & Systematics, Corson Hall.

At the Laboratory of Ornithology there exists an extensive collection of tape-recorded sounds of vertebrates, the Library of Natural Sounds, curated by James L. Gulledge. The library was begun in the early 1930s by two Cornell professors, Arthur A. Allen and Peter Paul Kellogg, who performed the first high-speed flash photography as well as acoustic recordings of frogs. This work resulted in the classic phonograph record "Voices of the Night," originally issued in a 78 RPM version in 1947 and republished by the Laboratory in 1982 in a completely revised 33-1/3 RPM edition. The herpetological tape collection at the Laboratory presently contains about 235 individual recordings of some 60 taxa, primarily frogs, toads, and crocodilians, worldwide in distribution. There are a large number of additional recordings in the unedited collection (mostly neotropical), and the collection is being actively enlarged for research purposes.



KRAIG ADLER and F. HARVEY POUGH
Division of Biological Sciences

Ithaca, New York 14853, U.S.A.

Editor's Note: The editor encourages faculty from other universities having programs in herpetology to describe same in a format similar to that above. In order to assure the timeliness of the material contained in such a feature article, authors should apprise the editor of their intention to submit a manuscript, and the proposed date of submission. ●

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

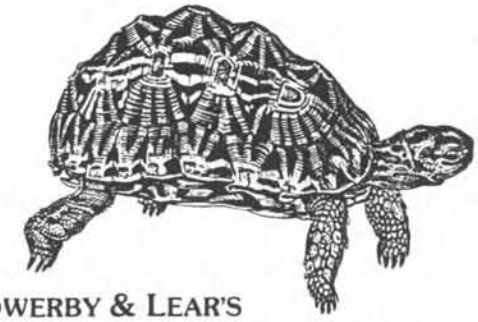
SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16'' thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24'' Reptile Cage $29.95

24'' Wide, 12¼'' High, 12½'' Deep
Approx. 250 sq. in. floor area
Single Vent

36'' Reptile Cage $53.95



36'' Wide, 18'' High, 19'' Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

JUST REISSUED

SOWERBY & LEAR'S

TORTOISES, TERRAPINS AND TURTLES

This book is generally regarded as the finest atlas of turtle illustrations ever produced, drawn by the famous nineteenth century artists James de Carle Sowerby and Edward Lear. The short text is by John Edward Gray. Originally published in London in 1872, the book was reprinted by the Society for the Study of Amphibians and Reptiles in 1970 but this edition was sold out some years ago. The reprint includes an extensive introduction by Ernest E. Williams, of Harvard University, detailing the history of the book and its authors and artists, and equating the scientific names to current nomenclature.

The atlas includes 61 black-and-white plates of turtles, depicting species from all parts of the world. The book measures 8½ by 11 inches (about 22 by 28 cm) and is clothbound. Copies can be purchased for $20.00 from the SSAR Publications Secretary, Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, U.S.A. The price includes postage in the U.S.A.; only the *additional* surface mailing costs will be charged for non-U.S.A. shipments. Payments from overseas should be made in U.S.A. funds, by International Money Order, or may be charged to MasterCard or VISA (include account number and expiration date of credit card).

SSAR also publishes *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Herpetological Circulars, Catalogue of American Amphibians and Reptiles, Contributions to Herpetology* and *Recent Herpetological Literature.* Inquiries about membership in the Society or purchase of back issues can be addressed to Dr. Taylor.

BOOK REVIEWS

Amphibians and Reptiles of the Pacific Northwest, by Ronald A. Nussbaum, Edmund D. Brodie, Jr. and Robert M. Storm. 1983. 332 pages. The University Press of Idaho. ISBN 0-89301-086-3.

The authors' stated aim is to provide a concise guide to identification of the species of amphibians and reptiles that occur in the Pacific Northwest. In this they have succeeded well. The geographic scope is Oregon, Washington, Idaho and British Columbia; 62 species (18 salamanders, 14 frogs, 2 turtles, 11 lizards and 17 snakes) of 37 genera and 17 families comprise the fauna. Species accounts, following a standard format, include: common name, scientific name and authority, photograph of the live animal, paragraph of general remarks (mostly recognition characters) and brief sections headed Habitat, Variation, Life History, Remarks (for some species), and References. There are introductory chapters entitled Introduction, Collecting and observing amphibians and reptiles, Composition and origin of the herpetofauna, Herpetology and Nomenclature. There is a brief description of each class, order, family and genus. There is an illustrated key to the salamanders, and for the frogs there are separate keys, one, illustrated by photographs, for metamorphosed forms, and the second, for tadpoles, illustrated by diagrammatic drawings. Each of the 62 species is illustrated at least once with a photograph; some are shown two or more times, in both color and black and white. For *Dicamptodon ensatus* for instance, the four photographs of a color plate show, respectively, a large adult, an adult in defensive posture, an albino larva, and a female guarding eggs, while a black and white photo accompanying the species account compares a larva with one of the less robust *Dicamptodon copei* from the same locality. The black and white photographs are of page width, are all originals of high quality, and all serve well to illustrate the general characters and aspect of the animal illustrated. Some serve also to illustrate aspects of behavior, habitat or life history.

Although all groups are competently dealt with, the authors are perhaps at their best in the accounts of salamanders and frogs. Three examples, the Pacific Giant Salamander *(Dicamptodon ensatus),* the Tailed Frog *(Ascaphus truei),* and Mary's Peak Salamander *(Plethodon gordoni)* must suffice to cite a few of the many interesting facts summarized in each species account. *D. ensatus* reaches a maximum length of 351 mm as a paedogenic larva. It varies geographically in voice (described as a rattling or growling sound), in defensive posture and behavior, and in the tendency to metamorphose or to remain a permanent larva. Terrestrial adults may feed upon small snakes, shrews, mice and salamanders, but invertebrates probably make up most of their food. The female guards the nest in a submerged and concealed chamber until the eggs hatch, a period as long as 200 days. The usual larval period is 18 to 24 months. *A. truei* is voiceless, mates in early Fall, underwater, with internal fertilization, sperm remaining viable in the oviducts for 10 months until oviposition. Usual clutch is only 44 to 75 eggs and females produce only in alternate years. Larval development lasts two or three years; young metamorphose August-September. *P. gordoni* may be only an unstriped morph of *P. dunni,* as the two occur in microsympatry, are similar biochemically. However, *P. gordoni* is slightly smaller, has an average of one less costal groove, a narrower head and longer legs.

The distribution maps show a surprising abundance and scattering of locality records, attesting to the rapid progress of herpetology in the Northwest in the 40 years since this reviewer's field work in the area. Some hasty approximate counts show the following numbers of locality records. For *Thamnophis elegans,* 138 in Oregon, 120 in Idaho, 94 in Washington, 70 in British Columbia; for *Elgaria coerulea* 95 in Oregon, 79 in Washington, 51 in British Columbia, 7 in Idaho; for *Ascaphus truei* 64 in Idaho, 52 in Washington, 42 in Oregon, 19 in British Columbia; for *Masticophis taeniatus* 31 in Oregon, 21 in Idaho, 8 in Washington.

For the distribution maps outline maps of two kinds were used. Those with Oregon, Washington and Idaho each occupy an entire page; those with these same three states and also British Columbia, used for the more northern species, are shown on a more reduced scale and occupy about 3/4 page. In each case the actual species range may occupy only a small part of the map, resulting in much wasted space that could have been used for text. Overall species ranges are not shown, and uninitiated readers will not know whether ranges stop at the Oregon and Idaho

boundaries or extend beyond, although this could have been shown with no loss of space.

Much significant new information is contributed for many of the species. The authors do well in distinguishing between their own original records and those from publications, and between published literature from the Northwest and that from other regions which might not apply in the Northwest. Few errors were noted. For *Crotalus viridis* varying litter sizes are reported for the subspecies *viridis, lutosus* and *oreganus;* for the latter the alleged "3 to 5" young per litter seems much too low in view of Klauber's (1956. Rattlesnakes, their habits, life histories... Univ. California Press) findings. For 79 *oreganus* litters that Klauber listed, mean was 6.6 (1-14). Likewise, for *Cnemidophorus tigris* the authors state that females from more southern areas, outside the Northwest, produce larger clutches (compared with the 2.65 mean of southern Idaho) with as many as eight eggs per clutch. Actually, the highest mean clutch size reported for a population of *C. tigris* is 4.1 (Goldberg, 1976, Copeia:260-266) for a montane population, and other samples from the southern half of the range average less than 2.5.

Amphibians and Reptiles of New England: Habitats and Natural History, by Richard M. DeGraff and Deborah D. Rudis. Illustrated by Abigail Rorer. University of Massachusetts Press, Amherst. 1983, 112 pp., 6 black-and-white photos, 56 drawings, 57 maps. $14.00 cloth, $6.95 paper.

In the first comprehensive survey of the New England herpetofauna in a very long time, the authors have undertaken the considerable task of synthesizing nearly 70 years of literature and documenting the distribution of 56 taxa. The book is intended for use by the scientific community, although it also will be interesting to amateurs.

The text is introduced by sections on the history of herpetological investigations, habitats present, and population status of rare species. The species accounts that follow discuss abundance, habitat use, breeding biology, home range, and food. Accompanying maps illustrate general distributions and denote county records with dots. There is a wildlife management emphasis to much of the book, which reflects the conservation background of the authors. I find this orientation timely, particularly in light of the recent emphasis by many state agencies on nongame wildlife programs.

Despite this useful perspective, the book is weak in aspects of its systematic and ecological coverage. I feel that one of the principal functions of a regional work is to document morphological characteristics of local populations. Yet, no original measurements were made, and there is little discussion of regional color patterns. The weak patterning of northeastern *Scaphiopus holbrookii* compared to southern individuals should have been documented, for example. Moreover, descriptions of habitats sometimes emphasize vegetation features that are of questionable importance to reptiles and amphibians. The heavy reliance on personal communications tends to promote this incomplete view of habitat use, and it results in habitat specificity being implied when it is not really present. For example, it is unlikely that old fields are a "special" habitat requirement of *Terrapene carolina*, or that *Crotalus horridus* is restricted to forests with high rodent density. Rodent density undergoes dramatic temporal fluctuation, and in any event current *Crotalus* distribution is more closely tied to recent historial factors (e.g. eradication campaigns). Statements about the important role of herptiles in insect and rodent control (p. 10) also seem a bit sweeping, particularly considering recent studies that suggest resource superabundance in the northeast.

Concerning evolutionary topics, the discussion of speciation in Ambystomid salamanders is unfortunately worded to sound as if reproductive isolation was caused *by* glaciation rather than having developed *during* glaciation. Furthermore, hybridization between *Bufo americanus* and *B. woodhousii fowleri*, so frequent on Cape Cod and in coastal Connecticut, is not discussed at all. A recent MS thesis completed at the University of Connecticut provides additional data on intergradation between *Chrysemys p. picta* and *C. p. marginata*.

The distributional data presented, although by far the best in print, suffers from an incomplete review of collections. Several major New England collections, including those at the Yale Peabody Museum (YPM) and University of Connecticut (UCM), were apparently not examined. Notable omissions were those of Connecticut specimens of *Ambystoma tigrinum* (YPM) and *Trionyx spiniferus* (UCM). Some UCM leopard frogs also appear to be *Rana utricularia* rather than *pipiens*. In addition, Cope's classic *Batrachia of North America* (1889; U.S. Nat. Mus. Bull. 34), with its wealth of New England data, was not consulted.

I found most comments on abundance reasonable. However, the uncommonness of *Thamnophis sauritus* is overrated; it is regularly found in marshes. Recent discoveries of some large *Ambystoma* cf. *laterale* populations also suggest that members of the *jeffersonianum* complex may be more common than previously thought. Additionally, further discussion of the extent of the rarity of *Eumeces fasciatus* and *Scaphiopus holbrookii* would have been interesting. Many feel that both these species are well on the way to extinction in New England. Finally, the tabular listing of *Desmognathus ochrophaeus* as rare in Connecticut (p. 8) is apparently a typographical error.

Even with the several shortcomings of the text, the authors are to be commended for their substantial compilation. They have summarized a great deal of regional literature and have included many original observations. Readers will find the comments section of the species accounts particularly enlightening. Individuals interested in the northeastern herpetofauna will find this a useful volume.

Dorsal Ventricular Ridge. A Treatise on Forebrain Organization in Reptiles and Birds, by P. S. Ulinski. 1983. 284p illus. John Wiley and Sons. $39.95

The dorsal ventricular ridge is a forebrain structure characteristic of the brains of reptiles and birds. It forms the lateral walls of the telencephalon and protrudes into the lateral ventricle. Functionally, the DVR forms a linkage between principle sources of sensory information to the telencephalon, i.e., from various receptors to structures in the brain that modulate behavior. An overall understanding of the uses of sensory information in modulating vertebrate behavior must rest ultimately in detailed accounts of each of the major variants of telencephalic structure and function, including DVR in the case of reptiles and birds. This important contribution should be of significant value to neuroethologists.

Their Blood Runs Cold: Adventures with Reptiles and Amphibians, by Whit Gibbons. The University of Alabama Press, P.O. Box 2877, University, Alabama 35486, 158 pp., 1983. $19.75 cloth, $9.95 paper.

I can't remember when I enjoyed reading a book as much as I did **Their Blood Runs Cold.** Whit Gibbons has interspersed science with wit, in a masterful way. The science is correct and aimed for the layperson, but don't buy the book for the science - buy it for the great stories of herpetologists in action. In this small volume Whit portrays the professional herpetologist as a scientist using his training to understand the natural history and evolution of this group of animals that few people understand and most people loathe. He also lays bare the trait found in so many field biologists (especially herpetologists) - the retention of the enthusiasm and a little of the craziness found in a group of teenage herpers on their first big snake hunt.

If you have ever crawled in the mud to collect a salamander; fallen into a pond going after a frog; suffered the indignities of backing into cactus collecting lizards; or been frightened nigh to death by a venomous snake, this book will speak to you. I made the mistake of trying to read it in my office and soon was surrounded by colleagues and students demanding to know why I was laughing uncontrollably.

Buy the book to read about Whit's "capture" of an eight-foot alligator that terrorized the staff of the Savannah River Ecology Laboratory. I would like to see Whit write a TV series of herpetological adventures and misadventures in the style of his gator story. I recommend **Their Blood Runs Cold** to all herpetologists, amateur or professional: if

you don't like this book turn in your snake-stick and potato-rake!

Catalogue of New World Amphibians, by Keith A. Harding. 1983. Pergamon Press. 406 pages. $80.00.

Most biologists fail to be aware of how rapidly new taxa are being found or of the number of systematic changes proposed for the highly diverse neotropical fauna. Biologists of every stripe require some readily available checklist in order to exploit organic diversity. The previous catalogues of American amphibians are badly out of date and out of print: Boulenger's two catalogues of amphibians were published in 1882, essentially at the beginning of his forty year dominance of herpetology. Persons needing information on organic diversity have had to make do with works of more limited coverage augmented with difficult searches through an ever-increasing sea of new literature. Harding's new book will satisfy a serious need.

The book is attractive and the binding sturdy enough for rough use by this reviewer. The pages are printed by offset of an original typescript but are attractive and easily read. The type is not overly small but varies only in that species names are italicized lower case whereas generic names are all italicized capitals and family group names are roman capitals. Major headings (order and chapter titles) are in yet larger type.

Harding's book consists of five parts. Section 1 (pp. 1-197) is a checklist of the American amphibians arranged alphabetically within families. Families and orders are arranged phylogenetically (see below). For each species and subspecies, the original usage is given as well as page reference to the description or proposal, the type-locality, and a limited statement of distribution (the country or countries in which the form has been reported). Harding includes countries into which the species was introduced (if the form is native to the Americas) without indicating that such distributions are introductions. Curiously, he does not report *Xenopus laevis* for the USA even though the species is established in California nor *Rana rugosa* for the Hawaiian Islands (except in the last case, in the geographic list). Such would be logical extensions of his reporting of various West Indian *Eleutherodactylus* from non-native areas, of *Bufo marinus* from the Old World, or of *Rana catesbeiana* and *Dendrobates auratus* from the Hawaiian Islands.

Section 2 (pp. 201-247) consists of geographic lists of species for each political unit (countries and islands). These lists were apparently generated by computer sorting—if the country occurs in the list of countries for the species' distribution, the species is listed in the geographic lists—and augmented by reports of the fauna of geographic areas (cited as 'Identification' following each geographic list; such references are intended to direct users of the Catalogue to keys which would aid in identifying specimens).

The third part (pp. 251-286) provides access to names now considered synonyms of other names. Harding's "Alphabetical Synonymy" is arranged alphabetically (within each order) by synonymous trivial name. All take the following form: "*hidalgoi, Cystignathus* Jiménez de la Espada 1875 = *Batrachyla taeniatus (sic)* Cei 1980." The original form of the name, its author and date, the name as used in the Catalogue, and the author and date who Harding follows (he frequently uses regional synopses or recent works rather than the reference wherein the synonymy or new combination was first proposed).

The fourth part (pp. 289-345) consists of full references to all works cited in the text (original descriptions, proposals of synonymies and new combinations, and identification guides). Unfortunately, not all the information contained in those references found its way into Harding's catalogue (e.g., Savage, 1974, is cited with regard to naming *Eleutherodactylus andi* but was apparently ignored in dealing with some of the synonyms of *E. fitzingeri* (i.e., *Hyla grisea, Hylodes palmatus,* and *Hylodes nubilis,* two of which are reported by Harding as recognized species of *Eleutherodactylus, nubilis* and *palmatus*) and its distribution (also found in Nicaragua).

The fifth part (pp. 349-406) consists of author and subject indices.

Although the book contains a few 1982 references, one cannot decide how trustworthy the literature search might have been. Harding provides no statement as to when he ceased to add to the manuscript aside from the date of 'October, 1982' in the Preface. I confess to being eclectic in my analysis of completeness but discovered a number of 'missed' references in the period 1980-1982 and relatively few prior to that. I view his catalogue as satisfactorily complete prior to 1980 but as uneven from 1980 to present.

In order to monitor completeness, I carefully sampled *Eleutherodactylus.* The genus *Eleutherodactylus* is the largest vertebrate genus and exclusively neotropical. In addition to its size, it is perhaps the most complex and interesting herpetological element in the Americas. Harding listed 387 species. I did not expect to encounter the six species of the genus named or one resurrected *(E. stejnegerianus)* in 1983, but the following named (date in parentheses) and recognized species are missing: *E. boulengeri* (1981), *E. brevifrons* (1981), *E. colostichos* (1982), *E. cuaquero* (1980), *E. grandoculis* (1904), *E. lineatus* (1879), *E. mimus* (1955), and *E. ruizi* (1981). Harding recognized the following taxa although each has been considered a synonym (synonym and date of proposal of synonymy in parentheses: *E. bufonoides (E. spatulatus,* 1970), *E. lineatissimus (E. mexicanus,* 1970), *E. nubilis (E. fitzingeri,* 1974), *E. oaxacae (E. mexicanus,* 1970), and *E. palmatus (E. fitzingeri,* 1974). For unknown reasons, he placed *Hylodes orientalis* Philippi, 1902, in *Eleutherodactylus* (for the first time), creating a secondary homonymy with *E. atkinsi orientalis.* I noted the following spelling errors: *bolbodactyla* for *bolbodactylus, crassidigitatus* for *crassidigitus, erythropleura* for *erythropleurus, lactea* for *lacteus, nigrogrisea* for *nigrogriseus, punctariola* for *punctariolus,* and *ricordi* for *ricordii* (such minor errors, disagreements in gender, pepper the book). Harding missed the synonymy of *Amblyphrynus* with *Eleutherodactylus* and the transfer of *Leptodactylus mantipus* to *Eleutherodactylus.*

The distributions given (countries only) contain several errors—*E. aaptus* (also Colombia), *E. buckleyi* (also Colombia), *E. cerasinus* (also Nicaragua), *E. chloronotus* (also Colombia), *E. conspicillatus* (not including Bolivia), *E. diastema* (also Ecuador), *E. elassodiscus* (also Colombia), *E. fitzingeri* (also Nicaragua), *E. glaucus* (not Guatemala), *E. gollmeri* (also Honduras, Nicaragua, Panama), *E. greggi* (also Mexico), *E. latidiscus* (excluding Panama), *E. leucopus* (also Colombia), *E. lymani* (excluding Brasil, Colombia), *E. matudai* (also Guatemala), *E. melanostictus* (also Panama), *E. nigrovittatus* (also Brasil), *E. noblei* (also Panama), *E. pseudoacuminatus* (also Colombia), *E. pygmaeus* (also Guatemala), *E. rubicundus* (occurs in Ecuador, not 'unknown'), *E. taurus* (also Panama), *E. terraebolivaris* (excluding Brasil, Colombia), *E. thymelensis* (also Colombia), *E. unistrigatus* (also Colombia), and *E. urichi* (excluding French Guiana). These errors are unfortunate inasmuch as the author views the geographic indices as "a distinct approach" presumably improving this document over the forthcoming World Checklist of the Association of Systematics Collections. Most of these omissions and errors can be retrieved from the references cited by Harding.

I am aware of 124 names proposed for *Eleutherodactylus* which are now considered as synonyms of other names. These include six names mentioned above, of which Harding recognized 5 as valid. Harding's "Alphabetical Synonymy" includes 78 of the 124 synonyms. The 37% he failed to include show no pattern of omission. The earliest was proposed as a synonym in 1870 and the latest in 1980; most were placed in synonymy between 1920 and 1970. Casual checks on other genera with which I have some acquaintance reveals comparable levels of omitted synonyms. The "Alphabetical Synonymy" is the poorest and least useful section of the book.

A potpourri of other omissions include (1) new taxa named before 1982: *Desmognathus santeetlah* Tilley, *Bufo atelopoides* Lynch and Ruiz, *Melanophryniscus cambaraensis* Braun and Braun, *Melanophryniscus macrogranulosus* Braun and Braun, *Argenteohyla altamazonica* Henle, *Hyla elkejungingerae* Henle, *Hyla leptolineata* Braun and Braun, *Adenomera griseigularis* Henle, and *Proceratophrys cristinae* Braun, (2) taxa restored to recognition: *Rhinoderma rufum* Philippi (see Formas et al., 1975, Physis), (3) generic transfers: *Atelopus proboscideus* to *Rhamphophryne* (see Izecksohn, 1976, Rev. Brasil. Biol.), and (4) incorrect usage of names: *Crepidophryne epioticus,* not *Crepidius epioticus* (change pointed out by Cope, 1889, Bull. U.S. Nat. Mus. 34:260), *Hylactophryne occidentalis,* not *Hylactophryne mexicanus* (change pointed out by Lynch, 1976, Herpetologica 32:444).

Several other omissions are of a different sort. For example, Duellman (1970), Monogr. Mus. Nat. Hist. Univ. Kansas, 1:173, 328) placed *Hyloscirtus* in *Hyla* and recognized the *bogotensis* group which he later (1972,

Occ. Pap. Mus. Nat. Hist. Univ. Kansas, 11:1-31) monographed. Lutz and Ruiz (1977, Bol. Mus. Nac. Rio de Janeiro, zool., 289:1) named *Hyloscirtus vermiculatus*. Presumably, Harding viewed Lutz and Ruiz's usage of *Hyloscirtus* as sufficient to ignore Duellman's view that the genus not be recognized. Duellman continued to name new species of the *bogotensis* group and to place them in *Hyla* (e.g., *H. torrenticola*). Harding's taxonomic decision in this instance was to ignore Duellman (1970) but accept part of later arguments (i.e., *H. torrenticola* is a *Hyla*, but of a group whose type-species is the type-species of another genus). Perhaps Harding wished to avoid creating a new combination for the species named by Lutz and Ruiz, which is now considered a synonym of *Hyla bogotensis*, *fide* Ruiz and Lynch, 1982, Caldasia, 13(64):650.

The systematic arrangement (four orders, Gymnophiona, Caudata, Meantes, and Anura; sequence for families; and apparently some generic assignments to subfamily) follows, curiously enough, Goin, Goin, and Zug's (1978) "Introduction to Herpetology" rather than original papers where data are discussed. For example, Harding placed the monotypic hylid genera *Anotheca* and *Nyctimantis* in Amphignathodontinae, probably following Duellman (1970). However, Duellman and Trueb (1976, Occ. Pap. Mus. Nat. Hist. Univ. Kansas, 58:1-14), who studied these frogs, concluded (albeit, in a vague way) that both genera must be placed in the Hylinae.

Many authors have discussed the phylogenetic arrangement of salamanders and most have rejected Cope's notion of a separate order for sirenids. The only place the notion persists is in the various editions of "Introduction to Herpetology" and now, Harding's Catalogue. One wishes that Harding had evaluated such works as Edwards (1976, J. Morph. 148:305-328), Estes (1965, Amer. Zool. 5:319-334), Regal (1966, Evol. 20:392-407), and Wake (1966, Mem. So. California Acad. Sci. 4:1-111) before critically adopting Goin et al. (1978). However, the salamander arrangement will not likely confuse users.

The phylogenetic arrangement for the larger and more diverse group, Anura, was taken likewise from Goin, Goin, and Zug (1978). This arrangement in turn was taken from Jay Savage's imaginative and provocative arrangement proposed in part without so much recourse to systematic as to biogeographic data and in part based on Starret's study of tadpole morphology (both published in 1973 in "Evolutionary Biology of the Anurans: Contemporary Research on Major Problems," edited by J. L. Vial). Starret's proposal received serious and unanswered criticism from Sokal (1975, Copeia, 1975:1-23, and 1977, J. Zool., London, 182:505-508). Few anuran systematists subscribe to Starret's arrangement, which although that doesn't make it wrong, certainly raises questions as to why Harding would promulgate it.

I am vexed less by use of Xenoanura, Scoptanura, Lemnanura, and Acosmanura than by use of the 'family' Allophrynidae (*sic*). In the former case one has recourse to data and arguments whereas in the latter one encounters no wisps of either. This ethereal family, presented as a group coordinate to other families by Harding and by Goin, et al. was never proposed, it simply appeared on stage one day and none of us noted the conjurer's art until Savage's paper appeared in the 1973 book edited by James Vial. *Allophryne ruthveni* may belong to its own family but, going by primary literature (in which data, arguments, and formal proposals are made), is merely a curious hylid (Lynch and Freeman, 1966, Univ. Kansas Publ., Mus. Nat. Hist. 17:493-502; Duellman, 1970, op. cit.:19-20; Duellman, 1977, Das Tierreich, 95:5-6). Its recognition as a family reminds me of an opposite case of decades ago. Davis (1936, Zool. Ser. Field Mus. Nat. Hist. 20:121), in discussing Bidder's Organ and recognition of both Bufonidae and Leptodactylidae remarked "In other words, Noble's reason for reducing them to subfamily rank (non-existence of a defining character) no longer remains." I've treasured always the implicit logic embodied in that sentence, i.e., if not definable by character or data, then the group is a subfamily. In this case, Allophrynidae (*sic*) was listed casually in a biogeographic analysis and set of hypotheses, never having been proposed as a family, and was adopted without stated rationale by an introductory textbook. Its continuing establishment, without being supported by evidence or formally proposed, offends my sense of scientific propriety. Its use in Harding's book undermines my confidence in his choices as to species recognition, family assignments, family sequence, and ordinal recognition when I cannot evaluate the original data. His use of a leptodactylid subfamily, the Hylodinae (*sic*), also follows Goin et al. (1978) who followed Savage (1973) in spite of Lynch's (1971, Misc. Publ. Mus. Nat. Hist. Univ. Kansas, 53:10) point that Günther's (1859, Catalogue of the Batrachia Salientia . . . British Museum, p. 90) Hylodidae was based on *Hylodes* of Fitzinger, 1843, not *Hylodes* Fitzinger, 1826, requiring that if the southeastern Brasilian frogs of the genera *Crossodactylus*, *Hylodes*, and *Megaelosia* are to be placed in their own family group, the name must be Elosiinae rather than Hylodinae (following the Rules of Nomenclature rather than common sense).

In the preface, Harding states that "The primary aim . . . is to provide a source of basic, but rapidly retrievable information . . ." He hopes it will be" . . . of use to the taxonomist, conservationist and dedicated amateur alike." It is less clear to me what its use might be to amateurs than to conservationists and taxonomists. The latter two groups are likely to be more concerned about completeness and correctness. Using *Eleutherodactylus* as a guide, the 387 species listed by Harding include six not now recognized, seven proposed prior to 1982 and still considered valid but not listed by Harding, and three listed by him in other genera, for an error rate of 4.1%. Twenty-six species have incomplete statements of distribution (error rate of 6.7%). As mentioned above, the alphabetical synonym has an error rate of 37%. Taxonomists will not be seriously misled unless they assume absolute accuracy. Conservationists, unlike taxonomists, are unlikely to question Harding's accuracy and might err but I doubt the errors would be serious. If the error rates for other groups are all lower than those for *Eleutherodactylus* then the book still will be of considerable use; I am not entirely sanguine in suggesting that error rates are generally low for groups other than tropical plethodontids and the 'treefrogs' (Centrolenidae, Hylidae, and Pseudidae).

Lastly, one must comment on the price of the volume. Is it worth $80? On page iv one finds explanations as to why the book was reproduced directly from the author's typescript (" . . . as economically and as rapidly as possible . . . . "). I did not receive a price from the Reviews Editor but confidently inquired of the price at a Lincoln bookstore. They reported that the "tentative" price was $80. Such a price had a chilling influence on my graduate students' enthusiasm and caused one to await the forthcoming World Checklist of Reptiles and Amphibians from the Association of Systematics Collections. I will find the book a helpful one because I am interested in all neotropical amphibian groups but feel very confident about the literature of only one.

JOHN D. LYNCH

Lincoln, Nebraska 68588, U.S.A. ●

The Snakes of Honduras, by Larry David Wilson and John R. Meyer, 1982. Milwaukee Public Museum Publications in Biology and Geology, No. 6. [iii], 159 pp., 96 figs., 6 tables, frontis. (color). Available from the Milwaukee Public Museum, 800 West Wells St., Milwaukee, Wisconsin 53233. $22.50, plus $1.00 for shipping and handling. A 10% discount offered to libraries and institutions, 40% to resellers and bookstores.

This 8 1/2 x 11 paperback with a marvelous color photo of *Bothrops schlegeli* on the front cover cannot fail to catch the eye of any herpetologist, regardless of specialty. More careful inspection will yield further rewards for anyone interested in tropical and subtropical American snakes, or simply in identification of Honduran snakes, or in systematics in general, or in the ecology of Honduras. How such a seemingly specialized work can appeal to such a broad spectrum of readers calls for explanation.

Reviews have previously appeared by the same authors for the 52 species of amphibians (1971) and 58 non-ophidian reptiles (1973) of Honduras. The 91 species of snakes now reported yields a total herpetofauna of 201 species as of the dates of publication. Actually the preface for the present work was written 8 March 1979, appearing in print some 3.5 years later. Very little had been published on the herpetofauna of Honduras prior to the involvement of those authors, beginning twenty years ago. Thus these summaries are highly significant contributions that go far toward elimination of the unknowns lying between Mexico-Guatemala to the northwest, and Costa Rica-Panama to the southeast, all much better known. No claim of finality can be made for current knowledge of Honduran herpetology even now, but it is in a far better state than existed prior to the 1970's.

Wilson's preface, briefly reviewing the field work that forms the foundation for the review of the snakes of Honduras, strikes a poignant

note, revealing an appealing streak of romanticism seldom evident in the coldly impartial contexts of research reports. The progressive exacerbation of political tension since that was written, superimposed over the rapid environmental degradation evident even then and continuing unabated now, warn that the golden age of scientific endeavor in Honduras, which Wilson and his colleagues so briefly enjoyed—although it was sensed as a lifetime—draws to a tragic end. It is not likely that **The Snakes of Honduras** will soon be superseded.

The account begins with an excellent, brief "description of the physiography, geology, climate and vegetation of Honduras" (abstract, p.2), illustrated with maps, photos and graphs. The bulk of the book consists of separate species accounts, each including "a partial synonymy, including all references dealing with the species in Honduras; a statement of the total geographic range; a description of the species based on its entire range, with parenthetical statements concerning the range of variation in Honduran specimens; a statement of ecological distribution of the species in Honduras; a list of locality records for the species in Honduras" (abstract, p. 2). A spot map for each species in the country, illustrations of dorsal pattern of selected species, and keys to families, genera and species are provided. The book ends with an analysis of distribution patterns (5 pp.), six tables (including physiographic, vegetational and altitude correlation of distribution), a brief epilogue (as of 25 June 1979), an abstract in Spanish, a supplemental list of ten localities not listed in the gazetteers of their previous synopses, and seven pages of "Literature Cited" (approximately 350 references). There is no index, and no coverage of "natural history" other than ecological distribution.

Most species accounts include a section on "taxonomic comments," mostly concerning nominal species and subspecies recognized by previous authors. They are of vast interest to students of species-group systematics not only of Honduras but of other Central American countries and Mexico. That section makes fascinating reading.

Thus the synopsis of the snakes of Honduras is much more than the usual presentation of factual information, although that is the major thrust of the book and is exhaustively thorough. It is also highly interpretive, taxonomically, of that information. Not since Bogert and Oliver's classic analysis of the herpetofauna of Sonora, Mexico (1945), has such an extensively critical taxonomic discourse appeared on the herpetology of Mexico and Central America. It is not only exhaustively thorough, hence valuable in that context regardless of conclusions, but it is also the first consistent application throughout an entire major reptile monograph of the philosophy of strong (although not rigid) species-group monotypy. That is, subspecies are rarely accepted, and then only when overwhelmingly confirmed. Although Wilson and Meyer accept subspecies in a very few species, in no instance are they given formal entry, by rubric, in their accounts. They practice the principles of what might be called the "Stringent" school of thought on subspecies, in common with a respectable minority of their colleagues, whereas the majority of herpetologists (and other vertebrate zoologists) adhere in general, perhaps largely in habit, to the principles of the "Indulgent" school. Wilson and Meyer defend their philosophy with some vigor and clarity, making it plain that workers in the future should think seriously about the rationality of what has become habitual in treatment of geographic races.

In these several ways the appearance of Wilson and Meyer's **Snakes of Honduras** is a major event in herpetology, and should stimulate all workers in herpetological systematics. It is a great step forward in factual information and summary, and marks a crossroads of decision, both personally and for the discipline. It deserves far wider attention than its title may attract.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Longevity records are not accepted for this section. Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Knoxville Zoological Park, P.O. Box 6040, Knoxville, Tennessee 37914.

SAURIA

CROTAPHYTUS COLLARIS COLLARIS (Eastern Collared Lizard). **REPRODUCTION.** Various aspects of the reproductive biology of collared lizards have been documented including the classic monograph by Fitch (1956. Univ. Ks. Mus. Nat. Hist. 8:213-274) and comprehensive studies by Trauth (1978. J. Herp. 12:461-470; 1979. Herpetologica 35:184-192). Although much is known regarding *C. collaris* reproduction, there are few reports which deal directly with clutches and pre-hatchlings. Recently, Smith (1983. Herp. Review 14:46) reported data on clutches and hatchlings of captive *C. collaris*. The following includes additional information on a clutch and pre-hatchlings of *C. c. collaris*.

On 10 April 1983 a male (110 mm SVL) and female (96 mm SVL) *C. c. collaris* were captured by hand at an abandoned rock quarry, 18.8 km W Denton along U.S. 380 in Denton Co., Texas. The lizards were placed in a 208 l terrarium containing limestone rocks and sand and fed various arthropods *ad libitum*. Courtship behavior and copulation were not observed but on 28 May (1045 to 1545 hrs) the female oviposited a clutch of 11 eggs without digging a nesting burrow. After measuring the eggs, four showed signs of damage; the remaining eggs were placed in a container of damp vermiculite at approximately 25° C. Despite careful handling and care to prevent molding, additional damage to incubating eggs occurred following measurements on day 32 and 58. One pre-hatchling collared lizard on day 32 and three on day 58 were placed in preservative. All lizards were alive prior to preservation. Egg and pre-hatching measurements are shown in Table 1. All measurements are in millimeters (mm) except where noted and provided as mean ($\bar{X}$) $\pm$ 1 standard error of the mean (SEM).

Trauth (pers. comm., 1984) has handled *Cnemidophorus sexlineatus* eggs roughly during collection without causing excessive damage. However, eggs may become more fragile as incubation proceeds due to less calcium or a reduction in calcium in the eggshells of some squamates (D. L. Cox, unpubl., Vasser College).

It is suggested that future attempts to hatch *C. collaris* eggs include only minimal disturbance to incubating clutches because of their extremely fragile eggshells. In the present case, molding of eggs was uncommon with most damage done while attempting to measure egg dimensions using a caliper.

Voucher specimens are on deposit in the Arkansas State University Herpetological Museum (ASUHM #'s 4048-4052).

Thanks to Drs. V. Rick McDaniel (Arkansas State University) for technical assistance and Stanley E. Trauth (Southern Methodist University) for reviewing this note.

Submitted by **CHRIS T. MCALLISTER**, Renal-Metabolic Lab (151-G), VA Medical Center, Dallas, Texas 76216, U.S.A. ●

PHELSUMA MADAGASCARIENSIS KOCHI (Koch's Day Gecko). **TWINNING.** Twinning in oviparous reptiles is not rare in snakes, but is rarely reported in lizards. Although isolated cases have probably been reported in lizards, a search of the literature was not fruitful. Certainly, even less common are joined monozygotic twin embryos.

On 22 August 1982, a solitary egg was laid by a Koch's Day Gecko *(Phelsuma madagascariensis kochi)* at the Tulsa Zoological Park. The egg weighed 1.2 g and had a diameter of 13.5 mm. The mean weight of eight previous eggs laid by the same female (none containing twins) was 1.35 g and the mean diameter of nine previous eggs was 13.2 mm. The egg was incubated at 28-32° C. When it failed to hatch it was opened revealing two dead but well preserved embryos joined at the dorsum of the heads (Figure 1). The combined weight of the embryos was 0.6 g. The total length of one twin was 28.6 mm with a snout-vent length of 13.6 mm. The total length of the second twin was 31.5 mm with a snout-vent length of 18.3 mm.

Figure 1. Twin *Phelsuma madagascariensis kochi* embryos joined at the dorsum of the heads. The caudal ends of the tails are absent, having been inadvertently severed in transit for this photograph.

SERPENTES

ARIZONA ELEGANS ELEGANS (Kansas Glossy Snake). **COLORATION.** An albino *Arizona elegans elegans* was collected 3 miles east and 1 mile north of Whitedeer, Carson County, Texas on 4 September 1965 by Mary Buchanan. The specimen is an adult female (477 mm SVL) that lacks all integumentary and eye pigmentation characteristic of a complete albino (Figure 1). This specimen is deposited in the West Texas State University Natural History Museum (WTSU 2802).

Dyrkacz (1981. Society for the Study of Amphibians and Reptiles Herpetological Circular No. 11) summarized other reports of albinistic Kansas glossy snakes. One was a juvenile female collected in the San Felipe Valley, Anza-Borrego State Park, San Diego, California which showed some trace of a brownish pink pattern. A hatchling was also collected near San Luis, R.C. but it was unclear whether the specimen showed any pattern. The nearest albino *Arizona elegans elegans* locality to our specimen was an adult male collected at Sand Prairie Natural History Reservation, Burton, Harvey Co., Kansas. This specimen was collected approximately 450 km north of our specimen's locality and was a complete albino.

Submitted by **F. C. KILLEBREW** and **T. L. JAMES,** Department of Biology, West Texas State University, Canyon, Texas 79016, U.S.A. ●

CEMOPHORA COCCINEA COPEI (Northern Scarlet Snake). **REPRODUCTION.** Few records concerning reproductive biology of *C. c. copei* have been published. Wright and Wright (1957, Handbook of Snakes of the United States and Canada, Cornell Univ. Press, Vol. 1, p. 115) summarized the available data. Additional information has appeared in Woolcott (1959, Copeia (3):263), Palmer and Tregembo (1970, Herpetologica 26(3):300-302), Brandner (1981, Herp. Review 12(3):79), Trauth (1982, Herp. Review 13(4):126), and Herman (1983, Herp. Review 14(4):119). Only Woolcott and Brandner provided measurements of hatchlings.

On the night of 20 June 1983, a gravid female scarlet snake (461 mm SVL, 513 mm+ total length) was collected on Apalachicola National Forest Rd. 13, 27.4 km E of Wilma, Liberty County, Florida. The snake was maintained in a small cage provided with a container of moist sawdust. Seven elongate white eggs, two of which were weakly adherent, were laid in the sawdust on 4 July 1983. Lengths of the eggs averaged 28.9 mm (range 27.2 - 30.8), width 13.1 mm (range 12.4 - 13.6), and weights 2.85 g (range 2.7 - 3.0). Blood vessels were visible through the shells of the freshly laid eggs.

The eggs were incubated at 24 - 26° C. in slightly moist sawdust in a 2-liter glass container stored on a shelf in the laboratory. All hatched on 24 - 25 September 1983 and the young were sexed, weighed (triple beam balance), measured, and preserved on 26 September 1983 (Table 1).

Table 1. Total length, Tail length, mass, and sex of hatching *Cemophora Coccinea Copei.*

Total Length	Tail Length	Mass	Sex
176 mm	28½ mm	3.3 g	male
177 mm	27 mm	3.3 g	male
173 mm	27 mm	3.4 g	male
168 mm	25 mm	3.2 g	male
183 mm	28 mm	3.6 g	male
174 mm	25½ mm	3.1 g	female
179 mm	25 mm	3.4 g	female
$\bar{X}$ = 176 mm	26.5 mm	3.3 g	

Tail lengths as a percentage of total lengths averaged 15.5 (range 14.9 - 16.2) in five males, and 14.4 (14.0 - 14.7) in two females. The young exhibited a variety of patterns, with some having black bands joining to form dorsal circles with white centers on the anterior body, while others appeared normal.

The adult female (NCSM 24056) and neonates (NCSM 24508-24514) were deposited in the North Carolina State Museum of Natural History.

Submitted by **ALVIN L. BRASWELL** and **WILLIAM M. PALMER,** N. C. State Museum of Natural History, Box 27647, Raleigh, North Carolina 27611, U.S.A. ●

COLUBER CONSTRICTOR PRIAPUS (Southern Black Racer). **FOOD.** The racer, *Coluber constrictor,* is well known for its catholic food habits and has been recorded as a predator on a spectacular variety of taxa including insects, anurans, lizards, lizard eggs, snakes, turtles, birds, bird eggs, and small mammals (Klimstra, 1959. Copeia 1959:210-214; Fitch, 1963. Univ. Kansas Publ. Mus. Nat. Hist. 15:351-468). This note documents an observation of a racer feeding opportunistically on fish eggs.

The University of Florida's Center for Aquatic Weeds maintains a facility 20 km NE of Gainesville, Florida, for the study and induced propagation of the grass carp, *Ctenopharyngodon idella,* which is being researched as a potential control agent for aquatic weeds. At the conclusion of spawning experiments, unfertilized grass carp eggs are customarily flushed from large holding tanks into a grassy area outside the main building. These hydrated grass carp eggs are gelatinous balls 4-6 mm in diameter. On 15 April 1982, at approximately 1400 h, one of us (FJA) observed an adult *Coluber constrictor priapus* (ca. 90 cm total length) positioned at the exit of the fish egg effluent pipe, successively dipping its head and biting into egg masses as they emerged. The snake paused briefly between feeding bouts to raise its head and tongue flick. This activity was observed for about 10 min before the racer saw the observer and fled.

The above observation is noteworthy because it demonstrates the resourcefulness of *C. constrictor* to make use of a food item that is not naturally available. Fitch (op. cit.) reported several semi-aquatic amphibian (*Rana* and *Hyla* spp.) and reptilian *(Chrysemys picta, Nerodia sipedon)* prey in the diet of racers, but no obligately aquatic prey (e.g. fish, fish eggs, larval amphibians, amphibian eggs). Although it is possible that naturally-occurring fish or amphibian eggs have been eaten by racers but not recognized from their stomach contents, such aquatic prey would be inconsistent with *C. constrictor's* strongly terrestrial habitat preference (Ditmars, 1936, The Reptiles of North America, Doubleday, Garden City; Schmidt and Davis, 1941, A Field Book of Snakes of the United States and Canada, G. P. Putnam's Sons, New York). Despite the unnatural occurrence of fish eggs in a terrestrial habitat, they were nevertheless recognized by *Coluber* as a potential source of food energy. This type of opportunistic foraging behavior is probably one of the factors responsible for *C. constrictor's* overall success and widespread geographic distribution.

Submitted by **DAVID G. COOK,** Department of Herpetology, Atlanta Zoological Park, 800 Cherokee Ave. SE, Atlanta, Georgia 30315 and **FREDERICK J. ALDRIDGE,** Center for Aquatic Weeds, School of Forest Resources and Conservation, University of Florida, Gainesville, Florida 32611, U.S.A. ●

CROTALUS VIRIDIS (Prairie Rattlesnake). **FOOD.** Three adult *Crotalus viridis* were collected from the National Bison Range, Lake County, Montana on 19 June 1983 consisting

of two females and one male. One of the female snakes (842 mm) was found to have a juvenile *C. viridis* (264 mm) folded in half in its stomach. Also in the gut were four voles *(Microtus montanus),* three large adults weighing 30-40 g each, and a juvenile weighing approximately 15 g.

Although there have been several reports of cannibalism in captive rattlesnakes, Klauber (1972. Rattlesnakes, their habits, life histories, and influence on mankind. 2d ed. Univ. Calif. Press) concluded that cannibalism among rattlesnakes in the wild is quite rare. In the few instances when it has occurred, the snake eaten had sometimes been dead before it was swallowed. It cannot be determined whether or not the young snake in this instance was dead before being eaten; the body and skin were still intact with minimal decomposition.

It has been suggested that in cases of cannibalism such as this the smaller snake may have been attempting to ingest prey that the larger snake swallowed (H. M. Smith, pers. comm.). There was no evidence suggesting that the juvenile snake was eaten simultaneously with any of the other items in the adult's stomach.

This specimen is being housed in the herpetological collection of the vertebrate museum at the University of Colorado, Boulder.

Submitted by **DAVID L. GENTER,** Department of Zoology, University of Montana, Missoula, Montana 59812, U.S.A. ●

CORALLUS CANINA (Emerald Tree Boa). **BEHAVIOR.** Agonistic behavior between male boid snakes has been documented by several researchers including Carpenter et al. (1978. Herpetologica 34:207-212).

On 18 January 1984, one adult female and two adult male *Corallus canina,* all previously separated, were placed together in an enclosure at the Oklahoma City Zoo Herpetarium. The enclosure measured 152 x 170 x 122 cm. Within several hours aggression between males was observed. Individual behaviors of chasing, mounting, and body writhe movements occurred. No biting was evident. These movements occurred on the floor of the enclosure and on horizontal branches of varying heights above floor level. After ca 15 min one male appeared dominant. For several hours thereafter the dominant male continued aggressing the subordinate male with the subordinate attempting to flee. Following this period the dominant male began to constrict the subordinate male. As opposed to prey constriction, where primarily the anterior portion of the body is used, the dominant male used the posterior portion of the body to constrict the neck area of the subordinate male. The subordinate male, although in apparent distress, was not observed to actively oppose this constricting behavior. To avoid physical damage, the subordinate male was removed from the enclosure. Reintroductions of the subordinate male or another male resulted in the same series of events with the exception that constrictions were observed on all portions of the subordinate males' body. The constricting behavior was only observed when both specimens occupied positions on the same or nearby horizontal branches. The dominant male was also observed on several occasions to aggress and constrict the adult female, a permanent resident in the enclosure.

This observation may be important in captive management of *Corallus canina* where a limited amount of space is available for retreat by subordinates.

Submitted by **STEVEN T. OSBORNE,** Oklahoma City Zoo, 2101 N.E. 50th, Oklahoma City, Oklahoma 73111, U.S.A. ●

HELICOPS ANGULATUS (South American Water Snake). **REPRODUCTION.** There appear to be only two literature accounts concerning reproduction in *Helicops angulatus (Trinidad:* Mole, 1924. Proc. Zool. Soc. London 1924:235-278; *Colombia:* Rossman, 1974. HISS News-J. 1:189-191), both of which reported instances of egg laying. Because the period from deposition to hatching was less than 2-1/2 weeks in the case of the Colombian specimens (unknown for the Trinidad clutch), I suggested that *H. angulatus* might prove to be facultatively ovoviviparous. The purpose of this note is to present evidence that such, indeed, seems to be the case and that *H. angulatus* thus represents only the ninth species of snake reported to exhibit reproductive bimodality (Tinkle and Gibbons, 1977. Misc. Publ. Mus. Zool. Univ. Michigan No. 154:1-55).

On 30 September 1974, Richard Thomas collected an adult female *Helicops angulatus* (LSUMZ 27337) between 105 and 110 km SW Puerto Maldonado, Depto. Madre de Dios, Peru. When he preserved the female (410 mm SVL), Dr. Thomas removed seven apparently full-term young (LSUMZ 27340-46) averaging 101 (97-104.5) mm SVL. These little snakes appear to be as well developed as the two hatchlings from Colombia and are comparable in length to the one that is not deformed (LSUMZ 22893; 103.5 mm SVL). No egg shells or obvious yolk were present, hence the evidence suggests that had this particular female *H. angulatus* not been collected when she was, she would have functioned as a live bearer rather than egg layer.

Submitted by **DOUGLAS A. ROSSMAN,** Museum of Zoology, Louisiana State University, Baton Rouge, Louisiana 70803, U.S.A. ●

LAMPROPELTIS MEXICANA (Nuevo Leon Kingsnake). **COLORATION.** A melanistic male *Lampropeltis mexicana (thayeri* morph) was hatched from a clutch of five eggs on 5 September 1982. The remaining four hatchlings exhibited normal coloration. The parents were siblings of a brood of eight normal patterned offspring from a melanistic female and normal patterned male, the originally collected stock. These snakes were collected in the Galeana area of Nuevo Leon, Mexico.

The melanistic offspring is overall black (including eyes) with underlying banding evident when held up to light. It behaves normally and feeds readily on lizards *(Eumeces)* and pink mice.

Considering the 1:4 ratio of the F_2, and based on several other wild-caught and captive-bred specimens I am aware of, it appears that this is a simple recessive trait with the Mendelian 1:2:1 ratio. Further reproduction must be carried out for more understanding of this trait. One point of interest is that of the few *thayeri* morph snakes that have been collected, several have been melanistic or heterozygous melanistic. The specimen is being maintained in the collection of Steven T. Osborne.

Submitted by **STEVEN T. OSBORNE,** Animal Technician in Herpetology, Oklahoma City Zoo, Oklahoma City, Oklahoma 73111, U.S.A. ●

RHINOCHEILUS LECONTEI ANTONII (Mexican Long-nosed Snake). **BEHAVIOR.** Male combat in colubrid snakes is a common occurrence that has been observed elsewhere (Shaw, C. E. 1951. Herpetologica 7:149-168).

On 6 July 1980 at 2300 h I observed combat between two male *R. l. antonii* in a cultivated field ca 85 km N. of Mazatlan, Sinaloa, Mexico. Both snakes were completely intertwined from head to tail. They were traveling at a rapid rate in a straight path across the field. The specimens became aware of human presence but rather than halting, simply changed direction and continued the behavior. After several minutes of observation the snakes were captured, probed, and found to be males.

Submitted by **STEVEN T. OSBORNE,** Oklahoma City Zoo, 2101 N.E. 50th, Oklahoma City, Oklahoma 73111, U.S.A. ●

TESTUDINES

PSEUDEMYS RUBRIVENTRIS (Red-bellied Turtle). **FOOD.** From 13-16 June 1983 ten gravid red-bellied turtles *(Pseudemys rubriventris)* ranging in CL from 288.8 - 306.6 mm ($\bar{X}$ = 299.9) were collected on the Tuckahoe-Corbin City Fish and Wildlife Management Area, Tuckahoe, Cape May County, New Jersey. These turtles were transferred to a child's plastic wading pool containing clean water on 17 June. Within two hours more than one individual defecated and one scat appeared to contain a blackened turtle shell fragment. Careful checking revealed several carapacial fragments in the dropping of one female (identity unknown). Six bones were subsequently recovered and identified as painted turtle *(Chrysemys picta)* peripherals and costals by George Zug (pers. comm.). The turtle from which they came was estimated to be about 120 mm in carapace length. In addition, a posterior neural from a much larger (> 200 mm CL) turtle was found. This bone closely resembles the sixth neural of red-bellied turtles in my collection. The circumstances under which the adult female red-bellied turtle ingested these shell pieces are unknown, but I speculate that scavenging on the remains of dead turtles is the most plausible explanation.

The Animal Research and Conservation Center of the New York Zoological Society provided travel support for this project.

Submitted by **TERRY E. GRAHAM,** Department of Natural and Earth Sciences, Worcester State College, Worcester, Massachusetts 01602, U.S.A. ●

STERNOTHERUS ODORATUS (Stinkpot). **REPRODUCTION.** On 7 March 1983, a female *Sternotherus odoratus* was collected by seining in shallow water of the Hillsborough River near Frog Creek, Tampa, Hillsborough County, Florida. The specimen had three growth annuli and a carapace length of 63.7 mm. On 18 July 1983, she deposited two eggs, measuring 22.2 x 13.2 mm and 23.4 x 14.2 mm. Ernst and Barbour (1972. Turtles of the United States. Univ. Kentucky Press. 347 pp.) state that females in the southern portion of the range lay from March through July and that clutch size ranges from one to four. They cite reports of eggs with measurements averaging 27.6 x 14.8 mm and 27.1 x 15.5 mm. The age of this female at deposition equals the youngest and the carapace length approaches the minimum of 61 mm (mean 82 mm) for reproductive females reported by Tinkle (1961. Ecology 42:68-76). Clutch size is within the range reported, though two for such a small female is unusual as clutch size and female body size are positively correlated.

The eggs were incubated on moist paper towels at temperatures ranging from 24 to 32° C. On 12 October 1983, the eggs were opened. The smaller contained a fully formed dead embryo with a carapace length of 18.5 mm, the larger egg contained only yolk. The smallest hatchling previously reported had a carapace length of 19 mm (Risley. 1933. Pap. Mich. Acad. Sci. Arts Lett. 17:685-711).

The hatchling has been deposited in the Bobby Witcher Memorial Collection (BWMC 02109) and the female is currently being kept in captivity at Avila College, Kansas City, Missouri 64145. Appreciation is extended to Donald D. Smith for reviewing this note.

Submitted by **ROBERT POWELL,** Department of Natural Sciences, Avila College, 11901 Wornall Road, Kansas City, Missouri 64145 and **STEVE PHILLIPS,** 2907 N. Dale Mabry, Tampa, Florida 33609, U.S.A. ●

STERNOTHERUS DEPRESSUS (Flattened Musk Turtle). **COLORATION.** Albinism has been reported in turtles on a number of occasions (reviews by Hensley, 1959, Publ. Mus., Mich. State Univ. 1(4):133-159; Ewert, 1979, *In* Harless and Morlock, Turtles: Perspectives and Research, Wiley and Sons, N.Y., pp. 333-413; Dyrkacz, 1981, SSAR Herp. Circ. 11:15-16). However, few instances of xanthism have been documented for turtles. Griffin and Ernst (1974, Herp. Rev. 5(4):105) described a xanthic *Pseudemys scripta* from Arkansas. Ewert (1979) reported another xanthic *P. scripta* and Harding and Latinen (1982, Herp. Rev. 13(1):19) described an "erythroxanthic" *Chrysemys picta* from Michigan. We here report another instance of xanthism in turtles.

On 23 August 1983, an unusually-pigmented juvenile *Sternotherus depressus* (Fig. 1) was captured on the Sipsey Fork of the Black Warrior River near the Sipsey River Recreation and Access Area, Bankhead National Forest,

Figure 1. Xanthic juvenile *Sternotherus depressus* (left); normally-pigmented juvenile (right).

Winston Co., Alabama. The specimen was captured while wading at night with lights in approximately one foot of water over a sand flat. Carapace length, width and height (in mm), respectively, at time of capture were 48.5, 44.0 and 12.0; weight was 15.0 g. Sex was undetermined and age was estimated by growth annuli to be three years.

Normally-pigmented juvenile *S. depressus* of this particular size have a brown carapace, with numerous dark spots or streaks, a flesh-colored plastron, and a greenish or light brown integument with a reticulum of dark markings (Fig. 1; Mount, 1975, The Reptiles and Amphibians of Alabama, Auburn Univ. Agricultural Experiment Station, Auburn). The overall color of our captured specimen is yellow-orange. The edges of the dorsal scutes and marginals are outlined in brown-black. Several dark spots are apparent on the carapace, with some very faint spots on the marginals, but all are much fainter and less numerous than in normally-pigmented individuals. The region of the carapace adjacent to the marginal scutes is slightly lighter and brighter yellow-orange than the more medial carapace area. Though there are faint stain marks on the edges, the plastron is generally light pink or colorless. The legs and tail are light yellow, but the thin integument near the edges of the shell are colorless. The claws are yellow. The color of the head and neck is slightly brighter yellow than the rest of the integument, closely matching that of the carapace. Brown blotches are present on the head and neck, but are not as dark or obvious as in typical specimens. The eyes are normally-pigmented, with dark pupils and a yellow iris. The animal is normal in morphology except that the anterior portion of the plastron is slightly asymmetrical, the right side being smaller.

Ewert (1979) discusses variations in turtle pigmentation. The suspected causes include both environmental stresses during incubation and genetic background.

The specimen is currently being maintained alive and well in the Biology Department at the University of Alabama in Birmingham. Upon its death it will be deposited in the University of Alabama in Birmingham Vertebrate Museum.

COX** Department of Biology, Samford University, Birmingham, Alabama 35229, and **CARL H. ERNST,** Department of Biology, George Mason University, Fairfax, Virginia 22030, U.S.A. ●

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

ANURA

BUFO WOODHOUSII FOWLERI (Fowler's Toad). USA: VERMONT: Windsor Co: White River Junction, Hillcrest Terrace. 22 April 1983. The specimen was photographed and released. Photograph deposited in Carnegie Museum of Natural History (Acc. No. 32489). Numerous sightings were made in the area throughout the summer of 1983. Photographs were verified by Drs. Lauren Brown, Illinois State University, Normal, IL.; Robert Mount, Auburn University, Auburn, AL; and Thomas French, The Nature Conservancy, Boston, MA. Specimen captured in residential neighborhood near area of northern hardwoods.

Although there have been several verbal reports of *Bufo woodhousii fowleri* in Vermont in recent years, mainly in the Connecti-

cut River Valley, this is the first tangible evidence of its occurrence in the state. Nearest records include the Merrimack River Valley, NH (Oliver and Bailey, 1939, *In* Warfel, Biological Survey of the Connecticut Watershed, Survey Report f:195-217), Albany County, NY (Bishop, 1923, Copeia, 1923:83-84; Stewart and Rossi, 1981, Amer. Midl. Nat., 106:282-292) and the Connecticut River Valley, MA (Dunn, 1930, Bull. Boston Soc. Nat. Hist., 57:3-8). The identity of specimens (4 tadpoles, Univ. Mich. Mus. Zool. 143170) reported from Hanover, Grafton County, NH, just across the Connecticut River from Norwich, VT (Oliver and Bailey, 1939) is now considered questionable.

RANA MUSCOSA (Mountain Yellow-legged Frog). USA: NEVADA: Douglas Co: area around mouth of Edgewood Creek where it empties into Lake Tahoe. Henry William Henshaw. October 1876. U.S. National Museum (USNM 8685). Cited by Cope (1899. Bull. U.S. Natl. Mus. 34:434) as *Rana temporaria pretiosa (=Rana pretiosa),* but reindentified by Linsdale (1940. Proc. Amer. Acad. Arts Sci. 73(8):210) as *Rana boylii sierrae (=Rana muscosa).* According to Yarrow and Henshaw (1878. App. L of App. N.N., Rept. Sec. War, Vol. II, pt. III, p. 1632) the specimens were collected at "Lake Tahoe" during (October) "1876". Lt. M. M. Macomb and supporting parties camped at Rowland's (on the SE shore of the lake) on September 26th, and proceeded to explore the Tahoe Range in the vicinity of Freel's Peak (Macomb. 1877. App. F. of App. N.N., Rept. Sec. War, Vol. II, pt. II, pp. 1278-1284). While the main party moved south, a small party (apparently including naturalist Henshaw) explored eastward in Hope and Carson Valleys almost to Genoa, returned by the Kingsbury Grade to Lake Tahoe, then moved south along the lake shore to Lake Valley, California. On the official expedition map (Topographical map of the Lake Tahoe Region, Sierra Nevada, California and Nevada. Expeditions of 1876 and 1877 under the command of 1st Lt. G. M. Wheeler. Issued June 30, 1881), only "Friday Creek" (=Edgewood Creek) is shown entering Lake Tahoe within the short length of shoreline between Rowland's and the California State boundary. This is probably the area where Henshaw collected his specimens. This locality is the first for the area southeast of Lake Tahoe (in Douglas County) and extends the range of the species 35 km south from Mt. Rose, Washoe County, Nevada (Zweifel. 1955. Univ. California Publ. Zool. 54(4):207-292: Zweifel. 1968. Cat. Amer. Amphib. Rept. 65.1-65.2). These records help document the historical presence of *Rana muscosa* around the whole of Lake Tahoe, which supports the contention that *R. pipiens* was introduced into the Tahoe Basin around the turn of the century (Bryant. 1917. Calif. Fish Game. 3(2):90; Storer. 1925. Univ. Calif. Publ. Zool. 27:1-343).

My thanks to Roy W. McDiarmid for providing information about these specimens.

RHINOPHRYNUS DORSALIS (Burrowing Toad; Sapo Borracho). NICARAGUA: Departmento de León: León Viejo. 1976. Collected (and later released) by Mauricio Zambrana. Identified by Jaime Villa from a photograph by José Angel Benavides. Photograph deposited in Carnegie Museum of Natural History (Acc. No. 32479). This toad is known from México to northwestern Costa Rica (Fouquette, 1969, Cat. Amer. Amphib. Rept., 78:1-2). On the Pacific coast of Central America records are few (Duellman, 1971, Herpetologica, 27:55-56), and (Villa, 1972, Anfibios de Nicaragua, 59-60). Most records come from moist forest environments; Duellman (*op. cit.*) recorded the first specimen from Nicaragua, collected in pine savannah at Waspám (outside the distribution area mapped by Fouquette). The León Viejo specimen comes from Tropical Dry Forest (also outside the area mapped by Fouquette), similar to the habitats of Costa Rican populations. Based on these few records it appears that *R. dorsalis* is not found exclusively in moist environments in the southernmost part of its range, but its fossorial habits and apparently relictual distribution make the sapo borracho a very elusive species.

ADDITIONS TO THE HERPETOFAUNA OF THE SOUTH COLORADO DESERT, BAJA CALIFORNIA, WITH COMMENTS ON THE RELATIONSHIPS OF *Lichanura trivirgata*

The Colorado Desert of northeastern Baja California, east of the Sierra Juárez and Sierra San Pedro Mártir south to the vicinity of Bahia de Los Angeles, is not well known biologically. The area is characterized by a lack of predictable rainfall and is one of the hottest places in the world (Meigs, 1953). Shreve (1934) remarked that this area may be the most sparsely vegetated of any area in North America. Climatic extremes combined with inaccessibility are major reasons for a lack of biological investigations in the southern portion of the Colorado Desert.

Slevin (1951) surveyed the herpetofauna along Highway 5 (Mexicali to San Felipe) but had poor results. Welsh (1976) and Seib (1980) considered the herpetofauna of the southern Colorado Desert to be depauperate due to climatic extremes. The purpose of the present paper is to report on a field collection from the southern Colorado Desert.

MATERIALS AND METHODS

From 29 April to 4 May 1979, we collected specimens in the northern part of the Valle de San Felipe, on a west to east transect from San Matias Pass (31°19'N, 115°30'W) to the junction of Highways 3 and 5 (31°25'N, 115°03'W; localities given as east of San Matias Pass), and south on Highway 5 to San Felipe (31°01'N, 114°50'W; given as north of San Felipe; Fig. 1). The transect covered about 91 km across the southern Colorado Desert from the Baja California Cordillera to the coast of the Gulf of California and included a variety of sandy flatland and rocky upland desert habitat. Collecting methods included nocturnal road driving, particularly along the newly paved eastern stretch of Highway 3 (Ensenada to San Felipe) between San Matias pass and the junction with Highway 5. In the morning hours, we captured lizards by hand, dust shot, or with a noose.

SPECIES ACCOUNTS

Coleonyx variegatus. Three specimens (USNM 225301-303) taken 15.7 to 26.2 km E San Matias Pass showed distinct pale nuchal loops and body bands characteristic of the Pacific coastal form *C. v. abbotti* (Klauber, 1945). These specimens support Welsh's (1976) contention that San Matias Pass and Valle de San Felipe are areas of intergradation between Gulf and Pacific slope populations of *C. variegatus.* A specimen from 16.8 km N San Felipe (USNM 225304) is a typical *C. v. variegatus.*

Petrosaurus mearnsi. Three specimens were collected in the Sierra San Felipe, 24.2 km E San Matias Pass, on Hwy. 3, 1.3 km S of Villa del Sol turnoff (USNM 225311-313).

Sauromalus obesus. One adult was collected in the Sierra San Felipe, 24.2 km E San

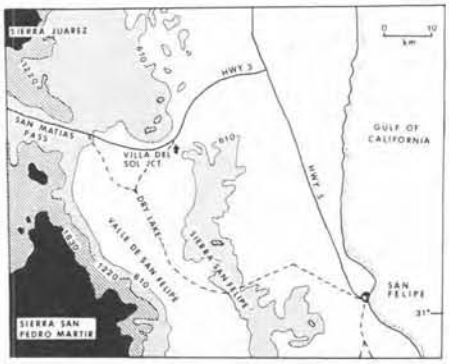

Figure 1. Major features of the south Colorado Desert, Baja California, Mexico. Elevations are in meters. Dashed lines are dirt roads; dotted lines enclose sandy areas.

Matias Pass on Hwy. 3, 1.3 km S of Villa del Sol turnoff (USNM 225317). These are the first records of *P. mearnsi* and *S. obesus* east of the Peninsular Cordillera. The Sierra San Felipe is an isolated mountain range of the Colorado Desert surrounded by sandy lowland habitat.

Urosaurus graciosus graciosus. One specimen (USNM 225326) was taken at the southeastern end of the Valle de San Felipe, 26 km by dirt road SE of the Villa del Sol turnoff. This is the third inland record for *U. graciosus* in the southern Colorado Desert and is 35 km NE of a specimen reported by Welsh (1976) from the mouth of Cañon Agua Caliente at the base of the San Pedro Mártir. We also observed *U. graciosus* at the base of the Sierra San Felipe (1.3 km S of Villa del Sol turnoff).

Uta stansburiana. We observed this common lizard along the base of the Sierra San Felipe. None were taken.

Dipsosaurus dorsalis dorsalis. One individual (USNM 225309) was collected in a sandy wash at the base of the Sierra San Felipe, 1.3 km S of Villa del Sol turnoff. Many others were observed along the Villa del Sol road, 2 and 8 km S of Hwy. 3, and one was found 6.6 km W of Hwy. 5 along Hwy. 3.

Phrynosoma platyrhinos. This lizard is common in Valle de San Felipe. We took specimens at three localities: 13.7 km S of Hwy. 3, along Villa del Sol road (USNM 225314); 5.4 km W of Hwy. 5, along Hwy. 3 (USNM 225315); and 3.2 km N of San Felipe on Hwy. 5 (USNM 225316).

Callisaurus draconoides rhodostictus. We collected specimens 26 km SE (USNM 225305-307) and 22 km SE (USNM 225308) of Hwy. 3 (Villa del Sol turnoff). These lizards were abundant in the large sand dunes on the east and southeast edges of the dry Laguna del San Felipe. Some dunes rise to about 15 m in height. These extensive areas of open sand are favored by *Uma notata*, but apparently this species does not occur as far south as Laguna de San Felipe (Slevin 1951; Pough 1977). Here *Callisaurus* apparently occupies the dune niche in the absence of *Uma*.

Gambelia wislizenii wislizenii. One adult (USNM 225310) was taken on the Valle de San Felipe road, 11.7 km S of Hwy. 3, in a flat area with scattered burro weed *(Franseria dumosa)* and saltbush *(Atriplex* sp.).

Sceloporus magister uniformis. We secured specimens from 26 km SE of Hwy. 3 (Villa del Sol turnoff), in the southeastern end of the Laguna de San Felipe (USNM 225320-323). They were found in vegetated areas on the flanks of the dunes or in hollows that were grown to thickets of palo verde *(Cercidium* sp.), mesquite *(Prosopis* sp.), and various bushes. At 9.8 km SE of Hwy. 3 (Villa del Sol turnoff), N end of Laguna de San Felipe (USNM 225324-325), these lizards occurred in hummock areas with mesquite and creosote *(Larrea tridentata).* We also saw *S. magister* at 1.3 km and 5 km S of Hwy. 3 (Villa del Sol turnoff). The species appears to be widespread in the region but is wary and difficult to catch.

Cnemidophorus tigris multiscutatus. One adult (USNM 225329) was taken 22 km SE of Hwy. 3 (Villa del Sol turnoff), in the dunes east of Laguna de San Felipe. The species was common on the flanks of the dunes and elsewhere in the Valle de San Felipe.

Xantusia vigilis. We found three lizards (USNM 225330-332) under debris and fallen yucca *(Yucca schidigera)* at 12.1 km E of Valle de Trinidad (12.2 km W of San Matias Pass), along Hwy. 3. These appear to be morphologically intermediate in dorsal pattern characters (Savage, 1952) between populations of central Baja California *(X. v. wigginsii)* and those of the southwestern United States *(X. v. vigilis),* as do *Xantusia* from the Sierra San Pedro Mártir region (Welsh, 1976). These specimens support Savage's (1952) evidence of a clinal pattern of variation in Baja California *X. vigilis.*

Lichanura trivirgata. We found a subadult (USNM 225337) 21.3 km E Villa del Sol turnoff (45.4 km E San Matias pass), along Hwy. 3. Gorman (1965) identified one specimen from 24 km N San Felipe as *L. roseofusca,* but omitted this locality on his range map. J. R. Ottley (pers. comm.) reported that this snake is from 25 km S San Felipe. Our specimen is the second record for northeastern Baja California. In pattern, coloration (Fig. 2), and ventral scales (Table 1), it most closely matches Klauber's (1931, 1933) and Stebbins' (1966) descriptions of *L. r. gracia.* Many of its scale counts (Table 1) fall within the range of *'roseofusca'* from Baja California and *'trivirgata'* from Baja California Sur, Arizona, and Sonora (Gorman 1965, Bostic 1971).

Stebbins (1966) stated that *L. trivirgata* is absent in extreme low desert from the Coachella Valley southward. The distribution of *Lichanura* apparently is spotty (Gorman, 1965, Stebbins, 1966) and further work in northeastern Baja California and northwestern Sonora may uncover new specimens. Our record is from an elevation of 270 m; such a low desert form may be expected to differ from animals farther to the west *(roseofusca* types), which occur in more mesic areas. The mountain range also may be a barrier to dispersal except across San Matias pass (elev. 980 m). Although *Lichanura* may occur up to 1,360 m, records in the Sierra San Pedro Mártir region indicate that it inhabits the lower Pacific slope and the San Quintín Plain west of the higher mountains (Welsh, 1976).

Ottley et al. (1980) reported one snake (no museum number and apparently alive) from El Arco, Baja California (28° 02'N, 113° 27'W),

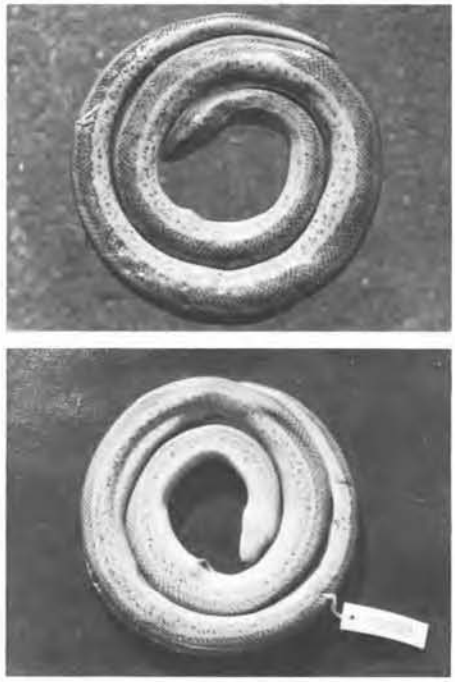

Figure 2. Dorsal and ventral view of *Lichanura trivirgata* taken in the south Colorado Desert. Tag on specimen shows field number (later cataloged as USNM 225337).

Table 1. Scale characters on some Baja California *Lichanura.* Mean with ranges given in parenthesis.

Location Source	Cape Region (Gorman, 1965)	San Marcos (Gorman, 1965)	San Ignacio (Gorman, 1965)	El Arco (Ottley et al., 1980)	Central Desert (Bostic, 1971)	This study
N	10	1	1	1	2	1
Dorsal Scale Rows	39.2 (36-41)	39	40	41	41 (40-42)	39
Ventrals	218.5* (219-223)	207	224	224	223.5 (222-225)	227
Caudals	45.0 (42-49)	41	44	48	44.5 (43-46)	46
Oculars one side	10.1 (9-11)	10	10	10.5 (10-11)	10.3 (10-11)	10
Supralabials one side	12.8 (12-14)	14	12.5 (12-13)	14.5 (14-15)	14.5 (14-15)	13
Infralabials one side	13.8 (13-15)	15.5 (15-16)	12.5 (12-13)	15.5 (15-16)	14.5 (14-15)	14

*Gorman's (1965) mean value (218.5) is apparently an error. Data are not available at this time to recalculate the correct figure.

that is intermediate in coloration and scale counts between *L. trivirgata* and *L. roseofusca* as recognized by Gorman (1965). However, the El Arco snake has few distinct features (ventrals, oculars, and infralabials) from specimens of *L. trivirgata* at San Ignacio or Isla San Marcos in Baja California Sur (Table 1).

Arizona elegans eburnata. Our records, the first for northeastern Baja California, are from 13.9 km E Villa del Sol turnoff, along Hwy. 3 (USNM 225338); 4.3 km E of San Matias pass, along Hwy. 3 (USNM 225339); 22.6 km N San Felipe, along Hwy. 5 (USNM 225342); 2.9 km S of the junction of Hwy. 3 (48.3 km N San Felipe), along Hwy. 5 (USNM 225343); 6.9 km W of Villa del Sol turnoff, along Hwy. 3 (USNM 225340); and 10.6 km E of San Matias pass, along Hwy. 3 (USNM 225341).

We assign these specimens to *A. e. eburnata*, which occurs to the north in the Colorado and Mojave deserts (Klauber, 1946a), and is known from the south by a single specimen collected at Rancho Rosarito on the Pacific slope at the southern end of the Sierra San Pedro Martir (Welsh, 1976). The subspecies *A. e. occidentalis* occurs along the Pacific side of Baja California as far south as El Rosario (Dixon and Fleet, 1976) and southeast near the junction of Hwy. 1 and the turnoff to Bahia de Los Angeles (Seifert, 1980). Intergradation between these forms likely occurs across San Matias pass.

Pituophis melanoleucus. One subadult (USNM 225363) was found 9.1 km E San Matias pass, Hwy. 3. This specimen matches Klauber's (1946b) description of *P. m. annectens*, a Pacific coastal form, except for the background coloration that is more characteristic of *P. m. affinis*, a subspecies of the Colorado Desert and areas farther east and south. There presumably is a zone of intergradation between Pacific and Gulf slope populations of the species across San Matias pass.

Phyllorhynchus decurtatus perkinsi. We found four specimens that match Klauber's (1940) description for the subspecies: 8.2 km E Villa del Sol turnoff (32.3 km E San Matias pass; USNM 225357); 1.1 km S Hwy. 3 (51.1 km N San Felipe), along Hwy. 5 (USNM 225358); 4.3 km W of Hwy. 5 (52.8 km W San Matias pass), along Hwy. 3 (USNM 225359); and 11.5 km E San Matias pass, along Hwy. 3 (USNM 225360). Welsh (1976) reported two other specimens from the Colorado Desert: 1.6 km N and 21.8 km N of San Felipe. The four new records verify the presence of the species across this section of Colorado Desert from the Gulf coast west to the mountain slopes.

Rhinocheilus lecontei lecontei. One specimen (USNM 225364) was taken 45.2 km E San Matias Pass, along Hwy. 3. This species is known previously in the south Colorado Desert from seven specimens from in and around the agricultural region near Mexicali and a single specimen from near San Felipe (Medica, 1975). The new record confirms its presence in the inland desert.

Salvadora hexalepis hexalepis. We found a single specimen (USNM 225365) 38.6 km E San Matias pass (14.4 km E of Villa del Sol turnoff), along Hwy. 3. This specimen confirms Bogert's (1945) speculation that the race *S. h. hexalepis* occurs in the Colorado Desert of Baja California.

Trimorphodon biscutatus vandenburghi. An adult (USNM 225367) was taken 9.9 km E Villa del Sol turnoff (34.0 km E San Matias pass), along Hwy. 3. This is the sixth specimen of the species known for Baja California, and the first report for the southern Colorado Desert (Welsh, 1976). The snake has an entire anal plate and 34 body blotches, thus matching Gehlbach's (1971) description for this race.

Chionactis occipitalis annulata. A series of six was obtained: 16.3 km N (USNM 225344), 18.1 km N (USNM 225345), and 18.2 km N (USNM 225346) of San Felipe, along Hwy. 5; 8 km W of Hwy. 5, along Hwy. 3 (USNM 225347); 0.5 km S of Hwy. 3, along Hwy. 5 (USNM 225348); and 11 km W of Hwy. 5 (46.1 km E San Matias pass), along Hwy. 3 (USNM 225349). Wake (1966) found the first Baja California record of *Chionactis* from 57.6 km N and 11.2 km W of San Felipe. Cross (1970) reported 11 specimens taken 1.6 to 52.8 km N of San Felipe along Hwy. 5, and all specimens were within 3.2 km of the Gulf of California coastline. We found no specimens farther inland than 14.2 km despite intensive driving along Hwy. 3. *Chionactis* may be restricted to the sandy coastal zone, but there is potential habitat for the species in sandy washes and in the extensive dune system around Laguna de San Felipe.

Our series is similar to other Baja California *Chionactis* in primary body bands, body bands plus unblotched ventral band positions (b.u.v.p.), and ventral and caudal scale counts (Table 2). Cross (1970) reported that the few *C. o. annulata* (11%) that had more than 44 b.u.v.p. are wholly from an Anza-Borrego population in southern California, but gives the range of b.u.v.p. for his 14 Baja California specimens as 31-51. The b.u.v.p. counts for our specimens are 45 or less. The primary bands are dark brown to black in the new series; Cross (1970) reported that the San Felipe animals had brown bands. Although Cross (1970) demonstrated some distinctive characters for the San Felipe population, the total known (N=21) from Baja California is small compared to other areas.

Masticophis flagellum piceus. We obtained two specimens east of the Sierra San Felipe: 4.6 km W of Hwy. 5, along Hwy. 3 (USNM 225353); and 15 km W of Hwy. 5, along Hwy. 3 (USNM 225354). We also saw snakes or found unsalvageable snakes at 12 km W San Matias pass, 2.9 and 21.9 km E Villa del Sol turnoff, and about 5 km W of Hwy. 5, all along Hwy. 3; and 24.3 km N of San Felipe. Wilson (1973) showed the species as widespread through the peninsula, but indicated only one previous record in the Colorado Desert near San Felipe. Our specimens were all red phase snakes.

Table 2. Comparison of Baja California *Chionactis*. Mean ± S.E. is given with range in parenthesis.

	Wake (1966)	Cross (1970)	This study
Sample size	1	14	6
Primary body bands	33	26.6 ± 0.8 (22-31)	26.0 ± 2.9 (23-31)
Body bands plus unblotched ventral band positions (b.u.v.p.)	42	39.7 ± 1.7 (31-51)	36.5 ± 5.6 (30-45)
Ventrals			
Males	145	149.5 ± 1.1 (143-154) N=10	151.5 ± 3.8 (146-156) N=4
Females		166 N=2	162.5 ± 3.5 (159-166) N=2
Caudals			
Males	46 + 1	44.2 ± 0.5 (42-47) N=9	43.7 ± 1.7 (42-46) N=3
Females		44 N=1	39.5 ± 4.5 (35-44) N=2

Crotalus ruber ruber. One individual (USNM 225374) was collected 20 km W of Hwy. 5, along Hwy. 3.

Crotalus mitchellii pyrrhus. Two specimens were taken at 1.3 km SE Villa del Sol turnoff (USNM 225372) and at the junction of Hwy. 3 and 5 (USNM 225373).

Crotalus cerastes laterorepens. Four sidewinders were taken along Hwy. 3: 22.9 km E (USNM 225368), 15.8 km E (USNM 225369), 2.4 km W (USNM 225370), and one km SE (USNM 225371) of the Villa del Sol turnoff. These records indicate that *C. cerastes* is common in the southern Colorado Desert up to 450 m elevation.

SUMMARY

In the winter of 1978-1979, northern Baja California received exceptionally high rainfall. In the spring of 1979 we found many reptiles in this region, including three species previously unreported and several others poorly represented in herpetological reports from northeastern Baja California. Our data indicate that the previous absence of some species in northeast Baja California, as compared with adjacent desert regions, is due to inadequate exploration rather than climatic extremes. Further, examination of this new material suggests that within some species there is genetic exchange between Pacific coastal and Gulf of California desert forms across San Matias Pass (980 m), the lowest gap in the northern Baja California Cordillera.

As with other species, there possibly is a broad area of intergradation of *Lichanura* across the San Matias pass. This area holds promise as a region where the distinction between *roseofusca* and *gracia* forms may be better defined.

We thank M. A. Bogan, C. Jones, J. R. Ottley, and H. M. Smith for providing helpful comments on the manuscript. The map was drawn by J. Whelan.

Animals were collected under permits issued by the Dirección General de la Fauna Silvestre (DGFS). This is a contribution to the biological investigations of Baja California, which is part of the DGFS/U.S. Fish and Wildlife Service Cooperative Agreement on Wildlife Research and Conservation.

All specimens are deposited at the National Museum of Natural History (USNM).

TECHNIQUES

A TECHNIQUE FOR INDIVIDUALLY MARKING FROGS IN BEHAVIOURAL STUDIES

There are a number of methods for individually marking anurans (reviewed in Ferner, 1979). Toe-clipping and tattooing are particularly useful in long term studies of marked populations. In behavioural studies, however, these techniques have the severe disadvantage that the frog has to be captured and its mark examined before its identity can be established. It is often impossible to be sure of the identity of the protagonists throughout a fight or courtship display.

In a behavioural study of bullfrogs, *Rana catesbeiana*, Emlen (1968) marked individuals with colour-coded elastic waistbands so that they could be identified without disturbance. I tried this technique on the following Australian hylids and leptodactylids: *Litoria aurea, L. raniformis, L. peroni, L. verreauxi, Limnodynastes tasmaniensis, L. dumerli, Uperoleia rugosa, U. marmorata, Pseudophryne bibroni* and *Neobatrachus sudelli*. In all cases the frogs would not tolerate the waistbands but attempted to shake the bands off by twisting, jumping and somersaulting. The larger hylids, particularly *Litoria aurea* and *L. raniformis*, began struggling as soon as bands were placed on them and did not stop until the bands were removed. The other species of frogs reacted to the bands more intermittently, but it was clear that the bands were disrupting their normal behaviour. It is also difficult to make waistbands small enough for the smaller species of frogs. I describe below a method which I developed for use in a behavioural research project on the breeding biology of the small (< 40 mm snout-vent length) leptodactylid *Uperoleia rugosa* in which it was essential to identify individuals without disturbance (Robertson 1982, in press and in preparation). This technique was only tested with *U. rugosa* but it is likely to work with other species.

Each frog was marked with a unique combination of one to three squares (c 1 mm x 1 mm) of Scotchlite® brand reflective sheeting (3M company) attached to the head. The head of the frog was first wiped dry with tissue paper and the reflective squares were glued in place with a fast-setting cyanoacrylate tissue cement (Ethicon Bucrylat). The frogs were also marked by excising the last digit of one to three toes in a unique sequence (Nace, 1974). The reflective squares would stay in place for up to ten days, which was sufficient for some short term experiments but not enough for long term studies. The reflective squares were apparently becoming detached because of the secretions from the skin glands under the adhesive. Freeze-branding the top of the head for 10 sec with a pressurised refrigerant (Lazarus and Lowe, 1975) inhibited the skin glands.

This method has been used successfully on about 100 individuals of *U. rugosa*. I did not always record when the reflective squares needed to be replaced, but in general they stuck to the brand for about three weeks and sometimes as long as six weeks. For 15 frogs on which I have detailed notes, the reflective squares remained attached for between 16 and 41 days ($\bar{X}$ = 26.27, S.D. = 6.49). The length of time that a reflective square remains attached will probably vary with other species of frogs but by experimenting with the timing of the freeze-branding it should be possible to attach the reflective squares for at least three weeks.

In combination with toe-clipping this is a useful method for identifying frogs in behavioural studies. Frogs can be identified without disturbance for several weeks and when the squares of reflective Scotchlite® sheeting fall off, the frog can still be identified from its toe-clips. The reflective squares can be replaced successfully after a fresh freeze-branding. The reflective squares shine well in the light of a head-torch and the frog can be identified at up to 5 m which is far enough away to avoid disturbance. The range at which the frogs can be identified can be increased by using binoculars or by attaching larger squares of reflective sheeting to the frogs. The frogs seem to suffer no ill effects from this marking technique and their behaviour was indistinguishable from that of unmarked frogs.

ARTIFICIAL NESTS FOR FEMALE GREEN IGUANAS

Extracting accurate data on egg clutches laid by green iguanas, *Iguana iguana*, at communal nest sites is important in many respects. Information on clutch size, individual egg measurement, and nest construction are necessary for our understanding of reproductive capacity and nesting behavior of females. Egg clutches are often difficult to find, and because females are known to dig complex, interconnecting tunnel systems (Rand, personal communication), correct identification of a particular female's clutch can be difficult if not impossible.

An artificial "laying device" was designed to make possible the quick recovery of freshly laid clutches, the accurate association of female with clutch, and the identification of variables that constitute an adequate nest site.

An enclosure 10.5 m (L) x 9.3 m (W) x 1 m (H) was constructed of corrugated zinc (Fig. 1). Wooden posts (5 cm x 5 cm x 2 m) supported the walls from the outside. The zinc walls were buried 30 cm in the ground and lined with a cement strip 25 cm wide to prevent nesting females from digging out. Four bamboo houses 100 cm x 60 cm x 60 cm, placed in the area, provided shade and hiding places for the iguanas. A pit (4.8 m x 2.8 m x 50 cm) was dug in the center of the enclosure, and then refilled with the now broken-up soil. Four "nest holes" 40 cm deep were started in the pit by hand.

Six gravid females, collected from a natural nest site in Summit Gardens, Parque Nacional Soberanía, Panama, were placed in the enclosure on February 2nd and 3rd, 1984. All females began to dig in the pit, and in several days produced an elaborate tunnel system. Within two days the number of holes had doubled and several tunnels were connected to each other (Fig. 2). Observations made daily between 1700 and 1900 h enabled us to identify females with numbered holes. Females #2-6 laid their eggs between 2/6/84 and 2/13/84 (Table 1). Because of the tunnel network, exploratory digging was delayed until at least two of the females had deposited eggs.

In the areas where females had dug and covered up a hole, excavation failed to yield any eggs. It was necessary to dig the pit out entirely before clutches from females #2 and #3 were found in two side walls of the pit. The pit had been refilled and dug out again before clutches from females #4, #5 and #6 were found underneath the cement strip along the perimeter of the enclosure. Each clutch required an average of two days to find, and none were located in the tunnels dug by the females.

Drawbacks of the set-up were: (1) Failure to locate eggs, (2) Failure to identify without a doubt the origin of the clutch, (3) Disruption of the nest area and females, (4) Excessive expenditure of time.

An artificial laying device was designed, and six of these were placed in the pit (Fig. 1). The device consisted of six 40 cm x 20 cm x 10 cm concrete blocks and two 30 cm long clay tubes (Fig. 3). The artificial nests were placed in the bottom of the pit and covered with 3 cm of dirt, after filling the laying chambers completely with dirt. The two clay tubes (outside diameter 20 cm, inside diameter 15 cm) were placed in line with the chamber opening to form the entrance tunnel, the floor of which was covered with 7 cm of dirt. The only visible part of the entire device was the top half of the entrance hole (Fig. 1), although the interior of a chamber could be viewed easily by removing one or both of the concrete blocks on top. Other conditions in the pit and enclosure were the same as before, but now the females had the additional choice of using the artificial laying devices for egg deposition.

At the time the laying devices were placed in the pit on 2/14/84, five gravid females were in the enclosure. The morning following installation, a clutch of 33 eggs from female #1 was discovered in the back of chamber #4. Two more females occupied devices #1 and #3. During the next three days, four additional clutches, removed from the chambers, yielded 176 more eggs. At least two females occupied chambers at all times.

After introduction of the artificial device egg deposition time was reduced from 6 days to 2 days. Time for recovering eggs has been reduced from 2 days for each nest, to less than five minutes. Immediately after introduction to the enclosure, gravid females enter the device. An observer can tell when a chamber is either occupied by a female or a clutch has been laid, by simply looking at the entrance way. Females that are in the device block the entrance entirely with excavated dirt from the chamber. Those that have laid eggs refill the tubes and remain outside the nest. All clutches we obtained had been laid in the very back of the chamber and were seen easily after removing the top blocks and clearing 1 cm of dirt within the chamber. The eggs were removed for artificial incubation (Miller and Werner, in prep.) and the chambers refilled for the next female.

The observation that females laid clutches under the cement strip, in the hard walls of the pit, in the devices, and in certain nest holes in the wild, suggests that a solid roof may be an important factor in nest construction. Boylan (in press), writes of captive female *Cyclura cornuta cornuta* digging tunnels and nests under logs and slabs of rock. Solid cover over the eggs prevents caving in and could protect clutches from predators and adverse environmental conditions, and may provide the appropriate environment for successful incubation.

Female green iguanas have been observed nesting in a wide variety of substrates including different mixtures of soil, sand, and even ashes and refuse in garbage dumps.

From our experiments it is evident that:

1) If an adequate nest is available to a female she will use it.
2) Substrate composition appears to be relatively unimportant.
3) The immediate use of the artificial nest chambers by the females leads us to believe that the structural requirements of the nest chamber i.e. solidity of the walls and roof is a decisive factor for the female.

It is anticipated that experiments during artificial incubation (Miller and Werner, in prep.) will give insight into the importance of humidity, temperature, and substrate for normal egg development and successful hatching, and that further investigation of nest construction will provide information on egg arrangement and immediate environment (air spaces) surrounding the eggs.

Captive management enables the experi-

Table 1. Date on which female was placed in cage, date when she laid, and number of days between placing female in cage and laying. The number of eggs and locality where she laid are indicated. For nest site location see Figure 1.

mentalist to explore the variables that affect the many behaviors of the green iguana. The artificial nest device has already provided many insights into nesting behavior, a way to keep accurate records on females and their respective clutches, and sufficient eggs for artificial incubation.

This low-cost and easy-to-install device can be used for a number of purposes.

1. CONSERVATION: In areas where appropriate nest sites are not available to females, laying devices can be constructed easily. In areas where female iguanas are killed for their eggs (Fitch, et al., 1982; Ruiz and Rand, 1981), laying devices can be installed in nest areas and eggs removed, while keeping the females alive for subsequent seasons.
2. REPOPULATION AND MANAGEMENT PURPOSES: Depending upon needs a defined number of eggs can be collected and incubated.
3. IN ZOOS: The device allows easy construction of a laying site in a limited sized exhibit.

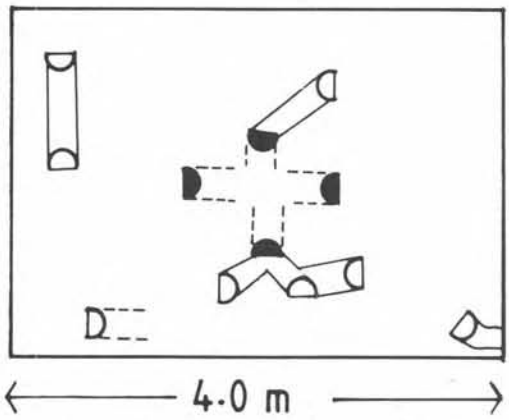

Figure 2. Natural holes (⌓) with tunnel network (⊏⊐) dug by females, and location of hand started holes (●). Dotted lines: exact destination of tunnel unknown.

We are confident that this laying device can be adapted easily to the needs of other species of reptiles by adjusting its size and location in a given area.

ACKNOWLEDGMENTS

The work described in this article was carried out within the scope of the Iguana Management Project (Part of the STRI Alternatives to Destruction Project), which is funded by the Alton Jones Foundation.

We would like to thank Raúl Fletcher, Director of the Parque Nacional Soberanía (ReNaRe) and Erasmo Vallester, Director of the Department of National Parks (Ministerio de Desarrolo Agropecuario), for logistic help and the use of the area. We are indebted to Wolfgang Nentwig for helping with data collection and helpful comments with the project. A. Stanley Rand has contributed information on female nesting behavior in green iguanas. Many thanks to Annette Aiello for editorial comments, and to Daisy I. Rey for secretarial help.

COMBINED MEETINGS

The 27th Annual Meeting of

THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

with

The 32nd Meeting of

THE HERPETOLOGISTS' LEAGUE

and

The 64th Annual Meeting of

THE AMERICAN SOCIETY OF ICHTHYOLOGISTS & HERPETOLOGISTS

AT

THE UNIVERSITY OF OKLAHOMA

Norman, Oklahoma

28 July - 3 August 1984

SYMPOSIA AND WORKSHOPS

Workshop in Larval Amphibian Biology (ASIH, SSAR), 30 July

Predator-Prey Relations in Lower Vertebrates (ASIH, SSAR), 31 July - 1 August

Biology of *Cnemidophorus* (ASIH, HL, SSAR), 1-2 August

Breeding and Care of Endangered Amphibians and Reptiles (SSAR Liaison Committee), 31 July

Regional Herpetological Societies Workshop (SSAR), 30 July

SPECIAL LECTURES

ASIH Presidential Address, Marvalee H. Wake, "Caecilians and I - Our First Twenty Years," 30 July

ASIH Distinguished Fellow Lecture, John E. Randall, "On the Importance of Marine Sanctuaries to Ichthyological Research," 30 July

HL Distinguished Herpetologist, David B. Wake, "Species, Genes and Morphology — A Perspective on Evolution in Salamanders," 30 July

ART AND PHOTO EXHIBIT (SSAR)

All meeting attendees are encouraged to bring their own herpetological or ichthyological art (paintings, drawings, sculptures) or photographic prints ready for display in the Stovall Museum gallery during the meetings.

LIVE EXHIBITS (SSAR)

The Oklahoma Herpetological Society will display live amphibians and reptiles from Oklahoma and nearby states in Richards Hall (Zoology) throughout the meetings. Attendants will be available to provide information and to assist persons who wish to photograph the animals.

COMMERCIAL EXHIBITS

Exhibits of appropriate equipment, publications and herpetological and ichthyological art for sale will be centrally located in Dale Hall, location of all scientific sessions. Authors of herpetological, ichthyological and related books are asked to encourage their publisher to exhibit titles (Contact: Neil B. Ford, Department of Biology, University of Texas, Tyler, Texas 75701, U.S.A.; telephone (214)566-1471, extension 206).

AUCTION (SSAR)

This popular and traditional event will be repeated this year. Proceeds will help support the annual meeting. All attendees are invited to donate books, art objects, posters, prints or other appropriate herpetological and ichthyological material. The chief auctioneer will be J. T. Collins. Receipts will be given for all items sold (tax-deductible). Material may be shipped to the local meeting chairman or brought to the meeting.

POSTER SESSIONS

Due to the large attendance expected members are being encouraged to give poster presentations rather than oral papers. Posters will be prominently displayed in the central lobby of the meeting area and will be scheduled in the program with times for authors to be present for discussion with interested viewers. Abstracts and titles required on official "call for papers" form.

AWARDS

Herpetologists' League: Best Poster Presentation

Herpetologists' League: Best Student Paper in Herpetology

American Society of Ichthyologists and Herpetologists Stoye Awards: Best Student Papers in general herpetology; general ichthyology; genetics, development and morphology; ecology, ethology and environmental physiology.

BUSINESS MEETINGS

ASIH-HL-SSAR Liaison Committee, 1900, 28 July

ASIH Executive Committee, 0900, 29 July

SSAR Board Meeting, 1000, 29 July

HL Board Meeting, 1300, 29 July

ASIH Board of Governors, 1500, 29 July

SSAR Business Meeting, 1630, 30 July

ASIH Business Meeting, 1630, 31 July

HL Business Meeting, 1630, 1 August

SSAR Board Luncheon, 1200, 2 August

SOCIAL AND EVENING EVENTS

Sunday, 29 July, 1930: Free Social and Entertainment

Monday, 30 July, 1700: Bus trip to Oklahoma City Zoo for free barbecue and open house tours.

Tuesday, 31 July, 1930: Presentations by David Dennis; an updated "Herpetologists: Then and Now," "Amphibians of the Southern Appalachians," and "Nature Photography Workshop."

Wednesday, 1 August, 1730: Picnic, Oklahoma Indian Dances, Auction.

Thursday, 2 August, 1900: ASIH Annual Banquet and Awards. Roast bison dinner (all attendees invited).

MEETING SITE

The University of Oklahoma main campus is in Norman, 18 miles south of Oklahoma City, near the center of the state. The Norman campus serves more than 21,000 students and the Norman community of about 70,000. All meeting activities on campus are within short walking distances of Dale Hall, which will house registration, all paper and poster sessions and business meetings. Free parking is available in a designated nearby area. Weather at this time of year is hot, dry and often windy. All meeting rooms, residence halls and eating facilities are air-conditioned.

ACCOMMODATIONS

Dormitory rooms with linen and blankets furnished ($16.00 single; $9.50 per person, double will be available in Adams Tower. Each room has two beds and each two rooms share an interconnecting bath. Several floors will be designated for families and quiet areas. Blocks of rooms at discount rates have been reserved at two local motels (not within walking distance of campus). Camping areas for tents and recreational vehicles are available at Little River State Park on Lake Thunderbird about 12 miles east of Norman.

MEALS

Registrants may eat in Couch Cafeteria where "all you can eat" fixed prices are $3.25 for breakfast, $3.50 for lunch and $4.50 for dinner. A variety of on- and off-campus eating facilities are available. Alcoholic beverages are available at some restaurants and clubs

and from liquor stores; beer is widely available.

FAMILY ACTIVITIES AND TOURS

Tours planned for families and spouses include trips to the Cowboy Hall of Fame and Kirkpatrick Omniplex Science Center in Oklahoma City and an all-day tour focusing on Oklahoma Indian culture to the Anadarko area. Child care facilities have been arranged at a local commercial child care center at reasonable rates; transportation provided.

PREREGISTRATION AND ABSTRACTS

The official meeting announcement and call for papers and preregistration forms was mailed to all of the sponsoring societies in late February and early March. **DEADLINES FOR RECEIPT OF TITLES AND ABSTRACTS IS *1 MAY.*** The official abstract form and call for papers information form included with the meeting announcement must be used for submissions. **THE DEADLINE FOR PREREGISTRATION IS *1 JULY.*** Due to the size and complexity of the meetings, the deadline will be adhered to strictly. The organizers urge an early submission of papers and preregistration. Preregistration after 1 July will cost an additional $5.00 per person. Registration fees before 1 July are: regular members, $35.00; student members $25.00; partner, spouse, $10.00; child, $3.00. Costs for the banquet and picnic are $14.00 and $5.50 per person, respectively. Any interested nonmembers may request the meeting announcement booklet and preregistration forms. Official registration badges will be required for all sessions and social events.

TRANSPORTATION

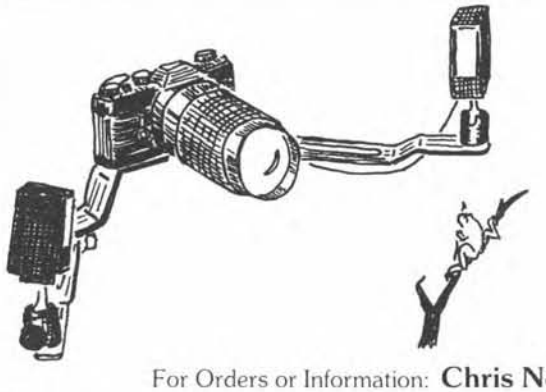
Air reservations should be made to Oklahoma City. Arrangements for special reduced fares ($6.00 one-way) have been made for limousine service for the 20-mile trip to Norman. Members should identify themselves as attending the "ASIH-HL-SSAR meeting at OU" at the limousine dispatch booth just outside the baggage claim area. Return ground transportation to the airport must be requested in advance on the preregistration form or at the meeting registration desk in Dale Hall.

MEETING CHAIRMAN

Victor H. Hutchison, Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019, U.S.A. Telephone: (405) 325-6721. ●

WORLD CONGRESS OF HERPETOLOGY

Planning for the first World Congress of Herpetology is proceeding on schedule. The Executive Committee, an international group of 17 persons, and the recently-elected 50-member International Herpetological Committee are now evaluating the criteria to be used in choosing a site and date, and discussing the format and content of the Congress. It is our plan to organize a Congress to be held in about 4 years that will be accessible to and of interest to all persons who study amphibians and reptiles. Potential hosts should contact the Secretary-General: Kraig Adler, Cornell University, Seeley G. Mudd Hall, Ithaca, New York 14853, USA. As soon as a decision on venue and date is reached, an announcement will be published in this journal giving the full details and the address to write for further information.



The Congress itself will be self-supporting, but in the meantime, during these all-important planning years, the organization will have considerable expenses—mostly printing and postage—yet it has, at the moment, no budget. The Committee has decided to raise the necessary funds by asking interested individuals to make a one-time contribution. Those persons donating 100 Dutch guilders (U.S. $35) would be named as "Sponsors," a designation that would appear in the formal program of the meeting; those able to contribute 1000 guilders would be designated "Benefactors." In the meantime, all such persons will receive copies of our *Newsletter* which will keep them informed of Congress planning activities. We hope that many colleagues will join with us in promoting herpetology on an international basis through the Congress. If you are able to do so your contribution can be made to one of our official accounts:

—POSTAL CHECKING ACCOUNT: Dr. M. S. Hoogmoed, Leiden, account number 5327161.

—BANK ACCOUNT: World Congress of Herpetology, Algemene Bank Nederland (A.B.N.), Leiden, account number 566274078.

—BANK ACCOUNT: World Congress of Herpetology, Marine Midland Bank, New York City, account number 006667341.

Contributions can be made in Dutch guilders to either account in Leiden or in U.S. dollars to that in New York. Checks may also be sent directly to the **Treasurer: Marinus S. Hoogmoed, Rijksmuseum van Natuurlijke Historie, P.O. Box 9517, 2300 RA Leiden, The Netherlands.**

MACRO FLASH-BRACKETS

For Sharper, Clearer Close-Ups

Lightweight, adjustable brackets
Allow use of two flash units to:

- Freeze movement
- Increase depth-of-field
- Control shadows

Fit any 35mm SLR camera
Standard Bracket (shown) $34.95
Omni-Directional Bracket $64.95
(flash units not included)

For Orders or Information: **Chris Neumann, 7338A N. Honore, Chicago, Illinois 60626**

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), occasional issues of **Facsimile Reprints in Herpetology,** and **Recent Herpetological Literature.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1984

Student member	$17.00*
Regular member	$22.00*
Sustaining member	$35.00
Contributing member	$50.00
Institutional	$40.00

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

with

The 32nd Meeting of

THE HERPETOLOGISTS' LEAGUE

and

The 64th Annual Meeting of

THE AMERICAN SOCIETY OF ICHTHYOLOGISTS & HERPETOLOGISTS

AT

THE UNIVERSITY OF OKLAHOMA

Norman, Oklahoma

28 July - 3 August 1984

SYMPOSIA AND WORKSHOPS

Workshop in Larval Amphibian Biology (ASIH, SSAR), 30 July

Predator-Prey Relations in Lower Vertebrates (ASIH, SSAR), 31 July - 1 August

Biology of *Cnemidophorus* (ASIH, HL, SSAR), 1-2 August

Breeding and Care of Endangered Amphibians and Reptiles (SSAR Liaison Committee), 31 July

Regional Herpetological Societies Workshop (SSAR), 30 July

SPECIAL LECTURES

ASIH Presidential Address, Marvalee H. Wake, "Caecilians and I - Our First Twenty Years," 30 July

ASIH Distinguished Fellow Lecture, John E. Randall, "On the Importance of Marine Sanctuaries to Ichthyological Research," 30 July

HL Distinguished Herpetologist, David B. Wake, "Species, Genes and Morphology — A Perspective on Evolution in Salamanders," 30 July

ART AND PHOTO EXHIBIT (SSAR)

All meeting attendees are encouraged to bring their own herpetological or ichthyological art (paintings, drawings, sculptures) or photographic prints ready for display in the Stovall Museum gallery during the meetings.

LIVE EXHIBITS (SSAR)

The Oklahoma Herpetological Society will display live amphibians and reptiles from Oklahoma and nearby states in Richards Hall (Zoology) throughout the meetings. Attendants will be available to provide information and to assist persons who wish to photograph the animals.

COMMERCIAL EXHIBITS

Exhibits of appropriate equipment, publications and herpetological and ichthyological art for sale will be centrally located in Dale Hall, location of all scientific sessions. Authors of herpetological, ichthyological and related books are asked to encourage their publisher to exhibit titles (Contact: Neil B. Ford, Department of Biology, University of Texas, Tyler, Texas 75701, U.S.A.; telephone (214)566-1471, extension 206).

AUCTION (SSAR)

This popular and traditional event will be repeated this year. Proceeds will help support the annual meeting. All attendees are invited to donate books, art objects, posters, prints or other appropriate herpetological and ichthyological material. The chief auctioneer will be J. T. Collins. Receipts will be given for all items sold (tax-deductible). Material may be shipped to the local meeting chairman or brought to the meeting.

POSTER SESSIONS

Due to the large attendance expected members are being encouraged to give poster presentations rather than oral papers. Posters will be prominently displayed in the central lobby of the meeting area and will be scheduled in the program with times for authors to be present for discussion with interested viewers. Abstracts and titles required on official "call for papers" form.

AWARDS

Herpetologists' League: Best Poster Presentation

Herpetologists' League: Best Student Paper in Herpetology

American Society of Ichthyologists and Herpetologists Stoye Awards: Best Student Papers in general herpetology; general ichthyology; genetics, development and morphology; ecology, ethology and environmental physiology.

Tuesday, 31 July, 1930: Presentations by David Dennis; an updated "Herpetologists: Then and Now," "Amphibians of the Southern Appalachians," and "Nature Photography Workshop."

Wednesday, 1 August, 1730: Picnic, Oklahoma Indian Dances, Auction.

Thursday, 2 August, 1900: ASIH Annual Banquet and Awards. Roast bison dinner (all attendees invited).

MEETING SITE

The University of Oklahoma main campus is in Norman, 18 miles south of Oklahoma City, near the center of the state. The Norman campus serves more than 21,000 students and the Norman community of about 70,000. All meeting activities on campus are within short walking distances of Dale Hall, which will house registration, all paper and poster sessions and business meetings. Free parking is available in a designated nearby area. Weather at this time of year is hot, dry and often windy. All meeting rooms, residence halls and eating facilities are air-conditioned.

ACCOMMODATIONS

Dormitory rooms with linen and blankets furnished ($16.00 single; $9.50 per person, double will be available in Adams Tower. Each room has two beds and each two rooms share an interconnecting bath. Several floors will be designated for families and quiet areas. Blocks of rooms at discount rates have been reserved at two local motels (not within walking distance of campus). Camping areas for tents and recreational vehicles are available at Little River State Park on Lake Thunderbird about 12 miles east of Norman.

MEALS

Registrants may eat in Couch Cafeteria where "all you can eat" fixed prices are $3.25 for breakfast, $3.50 for lunch and $4.50 for dinner. A variety of on- and off-campus eating facilities are available. Alcoholic beverages are available at some restaurants and clubs

and from liquor stores; beer is widely available.

FAMILY ACTIVITIES AND TOURS

Tours planned for families and spouses include trips to the Cowboy Hall of Fame and Kirkpatrick Omniplex Science Center in Oklahoma City and an all-day tour focusing on Oklahoma Indian culture to the Anadarko area. Child care facilities have been arranged at a local commercial child care center at reasonable rates; transportation provided.

PREREGISTRATION AND ABSTRACTS

The official meeting announcement and call for papers and preregistration forms was mailed to all of the sponsoring societies in late February and early March. **DEADLINES FOR RECEIPT OF TITLES AND ABSTRACTS IS *1 MAY.*** The official abstract form and call for papers information form included with the meeting announcement must be used for submissions. **THE DEADLINE FOR PREREGISTRATION IS *1 JULY.*** Due to the size and complexity of the meetings, the deadline will be adhered to strictly. The organizers urge an early submission of papers and preregistration. Preregistration after 1 July will cost an additional $5.00 per person. Registration fees before 1 July are: regular members, $35.00; student members $25.00; partner, spouse, $10.00; child, $3.00. Costs for the banquet and picnic are $14.00 and $5.50 per person, respectively. Any interested nonmembers may request the meeting announcement booklet and preregistration forms. Official registration badges will be required for all sessions and social events.

TRANSPORTATION

Air reservations should be made to Oklahoma City. Arrangements for special reduced fares ($6.00 one-way) have been made for limousine service for the 20-mile trip to Norman. Members should identify themselves as attending the "ASIH-HL-SSAR meeting at OU" at the limousine dispatch booth just outside the baggage claim area. Return ground transportation to the airport must be requested in advance on the preregistration form or at the meeting registration desk in Dale Hall.

WORKSHOP ON AMPHIBIAN LARVAL BIOLOGY

A teaching workshop on Amphibian Larval Biology will be held at the 1984 joint meeting of the American Society of Ichthyologists and Herpetologists, the Herpetologists' League, and the Society for the Study of Amphibians and Reptiles, University of Oklahoma, Norman, July 30, 1984. The workshop is designed as a minicourse for the non-expert on these organisms; no prior experience in herpetology or systematics is presumed. Among the people who may be interested in this workshop are general biologists, graduate students in herpetology outside of amphibian biologists, freshwater ecologists, developmental biologists and amateur herpetologists. The workshop will include the examination of museum specimens. A syllabus with annotated bibliography will be provided for all those who register. For more information contact:

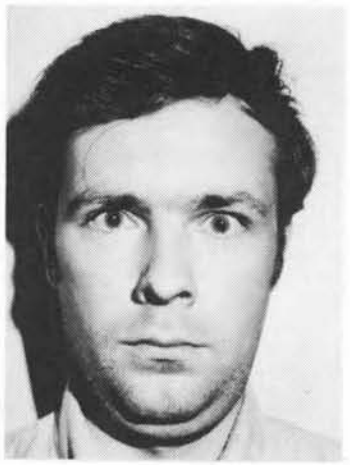
•



SNAKE REPORT *721*

Survey of 100 different snakes found in the Cameroons (West Africa). The book has over 700 photos, illustrations and diagrams, including a key of identification.

Survey of 650 pages published 1979 in English.

The book will be sent after reception of Eurocheck amounting to sFr 80.—. Orders are to be sent to: HERPETO VERLAG, Stucki-Stirn, 3623 *Teuffenthal* Switzerland

WANTED

SLIDES of HERPETOLOGISTS

I AM REVISING MY MULTI-SCREEN SLIDE SHOW ENTITLED "HERPETOLOGISTS THEN AND NOW", WHICH WILL BE PRESENTED AT THE SSAR, HL, ASIH MEETINGS IN NORMAN, THIS JULY.

YOUR HELP IS VITAL TO THE PRODUCTION OF A GOOD SHOW. I NEED SLIDES OF AS MANY HERPETOLOGISTS AS POSSIBLE. IF YOU HAVE FUNNY OR EMBARRASSING SLIDES (NO PORNO PLEASE!) SEND THEM TO DAVID DENNIS, GENERAL BIOLOGY SECTION, THE OHIO STATE UNIVERSITY, 1060 CARMACK ROAD, COLUMBUS, OH 43210.

IF AT ALL POSSIBLE SEND DUPLICATE SLIDES.

REMEMBER, YOUR FRIENDS WIL BE SENDING SLIDES OF YOU!

P.S. I CAN ALSO USE BLACK AND WHITE AND COLOR PRINTS! GRAD STUDENTS! YOUR ANONYMITY WILL BE PRESERVED.

WANTED

SSAR ELECTION RESULTS

The results of the 1983 SSAR Election are as follows:

President-Elect: George Pisani
Secretary: James Jacob
Treasurer: Henri Seibert
Board - Regular: Alan Savitsky
Board - Overseas: Timothy Halliday.

All three proposed amendments to the SSAR Bylaws (see *Herp. Review*, 14(1):5-6) passed.

The Society extends its gratitude to the Nominating Committee (James L. Vial, Chair) for its hard work, and to the outgoing President and Board Members for their service during their terms. ●

SSAR CONTRIBUTORS

Again we are happy to recognize those members of SSAR who have contributed during 1983 to the financial welfare of the Society. Their generosity is appreciated.

NATURE PRINTS

BY DAVID M. DENNIS

We are pleased to offer four exquisite, full-color art prints by David M. Dennis, naturalist and professional scientific illustrator renown for his watercolors of unusual wildlife.

Plate 1: *Green Frog and Damselfly*
Plate 2: *Painted Turtle and Dragonfly*
Plate 3: *Spotted Salamanders in Courtship*
Plate 4: *Red Salamander and Hercules Beetle*

Prints measure 20 x 24 inches (51 x 61 cm), each signed and numbered by Mr. Dennis in editions limited to only 500 copies. $30 each or $95 for set of four prints plus shipping ($4.50) and any New York taxes.

Send orders to BIOGRAPHICS, 12 Eagles Head Road, Ithaca, NY 14850. Color brochure published in *Herpetological Review* (March 1983 issue) and *Wildlife Publications Review* (June 1983 issue), or available on request from BIOGRAPHICS.

LETTERS TO THE EDITOR

OF PROPOSALS AND NOTICES AND NEWSNOTES: A RESPONSE

Having worked through the governmental maze in the Endangered Species Program for slightly over 7 years now, I had thought that I was aware of Federal activities throughout the Program. Imagine my surprise at finding in Herpetological Review a Newsnote to the effect that there were 110 amphibians and reptiles proposed for addition to the U.S. List of Endangered and Threatened Wildlife (Casper, 1983; 14(3):61). Amazing, thought I! I knew of course that there was (is) an attempt to circumvent the Washington office from the decision making process as part of putting more authority into field offices, but how in the world could such a momentous proposal escape my notice, much less not knock the telephone right off my desk from the legions of angry fellow scientists afraid of having their entire research programs wiped out. Best read on, thought I recovering slightly, as someone has assuredly botched Basic Reading. And indeed they did.

Let me assure all herpetologists that the Fish and Wildlife Service (FWS) has not proposed any species in the December 30, 1982, *Federal Register*. What the Service did was to prepare a notice of review of 110 reptiles and amphibians that need to have their status assessed or that *no longer need* status reviews. In fact, the amphibians and reptiles were included along with a rather comprehensive review of all native vertebrates that should be considered for further research activities. It is likely, and indeed we hope, that nearly all these species will not be listed, not because in someone's eyes they might impede his (her) ability to keep a pet snake, but because the status of the species is such that it biologically does not merit Federal protection.

In the text of the Newsnote, Casper did indeed note that the vertebrate species listed in the Federal notice were "being considered" for listing, but even this is not entirely true since there were 5 taxa listed as extinct and a number of additional species were included that are not being considered because they had taxonomic problems, were hybrids, or had previously appeared on Federal notices but were no longer being considered because they were found to be more abundant than previously believed, or without threats. Only 9 of the taxa were believed to qualify under the extremely stringent requirements of the Endangered Species Act for listing, and indeed we may need some more work on some of them to refine our knowledge of distribution, threats, or other pertinent information.

The vertebrate notice was not the first wide ranging notice to be published by the Service; several plant notices have appeared the past few years and an invertebrate notice is scheduled shortly. The purpose of these notices is to let the public, and particularly the scientific community, know what species are under consideration so that we may obtain the best information available on their status. If individuals have data which they believe can help us to evaluate status, we need to know about it so that future notices can reflect an accurate assessment of species. The 1982 notice has already pinpointed at least one omission, as well as provided us with new data which will allow a more accurate revision of the various categories. For instance, the Lake Erie water snake *(Nerodia sipedon insularum)* should have been included in the notice, while it seems that the Arizona ridgenosed rattlesnake *(Crotalus w. willardi)* should now be regarded as category 3C (no longer in need of review as a Federal candidate). Future vertebrate notices will reflect appropriate changes based on data, not opinion, as the evaluation of the status of species moves from a pseudoscience to a challenging field in its own right.

The overwhelmingly most disturbing thing about Mr. Casper's apparently unreviewed Newsnote is that his personal opinion ("Persons working with the proposed *(sic)* taxa should be aware that listing often hampers captive propagation (or other research programs); . . ." was accepted on a page of a

Society publication that is not an editorial page, but a place to let the herpetological community know what is taking place that might be of interest. This could easily have been edited to reflect a non-biased (and I might add, accurate) account of the Fish and Wildlife Service's vertebrate notice. It is also this kind of detrital material that detracts from many of the amateur society publications and certainly has no place in *Herpetological Review*.

For his personal edification, Mr. Casper should in future learn about the program he criticizes before he pontificates about listing being a deterrent to research. He should contact the Fish and Wildlife Service Federal Aid Program which administers cooperative agreement funds to the States under Section 6 of the Act for research on endangered or potentially endangered species; he might learn that several million dollars have been spent on amphibians and reptiles alone (see *Herp. Rev.* (11(3):70-72). Or he might have contacted either the Washington or the FWS Regional offices of Endangered Species where he might learn that several hundred thousand dollars have been spent in direct grants-in-aid for research on potentially endangered or threatened species on non-glamorous amphibians and reptiles; or he might contact the Fish and Wildlife Service office in Albuquerque which has just reported spending several hundred thousand dollars on sea turtle research; or he might contact the Service's Denver Wildlife Research Center (DWRC) to learn of their endangered species research program and how biologists have been brought from other countries to learn about crocodilian biology taught by DWRC personnel in part through Section 8 of the Endangered Species Act; or he might contact the Division of Realty and learn that key properties on Key Largo, and in the U.S. Virgin Islands, San Joaquin Valley, and near Plymouth, Massachusetts, to name a few, have been purchased specifically for amphibians or reptiles as a direct result of listing; or he might contact the Division of Law Enforcement to learn of the vast smuggling and illegal trade in reptiles and parts and products thereof, and how listing tries to put a dent into it; or he might contact the Houston Zoo or Auburn Cooperative Wildlife Research Unit to learn of *real* research on captive propagation of amphibians and reptiles; or he might contact me to learn that the Fish and Wildlife Service has, through the listing of endangered and threatened species, sponsored or cosponsored numerous scientific conferences to discuss the needs for both basic and applied biological research. Enough, I have made my point although I have barely scratched the surface.

In the future, I would hope that *Herpetological Review* will maintain the highly professional standards that it has held in the past, albeit a curious mix of research reports, news, and information. To those who follow Federal endangered species activities, know the program before you criticize it; it is indeed many faceted and quite complex. However, much good is accomplished for scientific research and the understanding of both species and herpetological communities. And finally, when questions arise, consult those who know most about the Program, either myself or one of the biologists in the Fish and Wildlife Service's Field or Regional offices, or the SSAR Conservation Committee. A professional society does not need the gamesmanship implied by Casper. Copies of the 1982 Vertebrate Notice of Review (*Fed. Reg.* 47(251):58454-58460) may be obtained by writing to: Office of Endangered Species, U.S. Fish and Wildlife Service, Washington, D.C. 20240.

Office of Endangered Species
U.S. Fish and Wildlife Service
Washington, D.C. 20240

REPLY TO DODD CRITICISMS

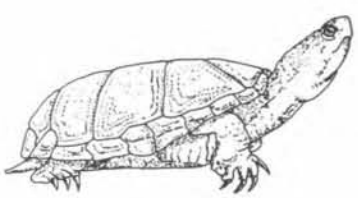
C. Kenneth Dodd, Jr.'s article "Of Proposals and Notices and Newsnotes: A Response" is highly critical of my Newsnote "New Federal Listings Proposed for Reptiles and Amphibians." His criticisms are based on faulty inferences, misinterpretation, and misinformation which makes his article unjustifiable and unwarranted. The shortcomings of Dodd's article are as follows.

Dodd claims that my Newsnote misrepresented the notice in the *Federal Register* (that I "botched Basic Reading") by claiming that 110 amphibians and reptiles were proposed for addition to the U.S. List of Endangered and Threatened Wildlife. Dodd goes on to say that the Fish and Wildlife Service (FWS) "has not proposed any species" but has "prepared a notice of review." In fact, my Newsnote clearly states in the opening sentence that "the FWS *published a review* of vertebrate wildlife *being considered for listing* as endangered or threatened species" (emphasis added). My next sentence stated that "52 amphibians and 58 reptiles are *listed in the proposed rules*" (emphasis added). This is an accurate count of the number of taxa listed in the *Federal Register*, vol. 47, no. 251, Proposed Rules *(sic)*, pp. 58454-58458. Dodd's claim that my Newsnote stated there were "110 amphibians and reptiles proposed for addition to the U.S. List of Endangered and Threatened Wildlife" is thus false.

Dodd goes on to refute this claim which I did not make, pointing out that not all of the 110 listed taxa were in the review category. This was already clearly stated in the third sentence of my Newsnote, which enumerated the number of taxa listed in other categories of the notice of review. The number of taxa in category 3B (not being considered for taxonomic reasons) was not enumerated because the original manuscript submitted to *Herpetological Review* reproduced the entire list of taxa in the Proposed Rules, including a complete description of the various categories, and as only 3 taxa were listed in category 3B it was unnecessary to include these in the brief introductory summary.

Dodd next defends the purpose of publishing the vertebrate notice, which is "to let the public, and particularly the scientific community, know what species are under consideration so that we may obtain the best information available on their status." This is the very reason I published the Newsnote, which encourages readers to contribute information to the FWS. I discovered the notice of review by accident 9 months after publication and found that herpetological and zoo circles were completely unaware of it. It seems strange that the FWS did not notify the zoological community of such an extensive notice requesting information from the public. Dodd's defense of the vertebrate review publication is unnecessary and irrelevant. No one disputes the dissemination of this information.

Dodd next takes issue with my statement that "listing often hampers captive propagation (or other research) programs," calling it "overwhelmingly disturbing," a "personal opinion," and "detrital material" with "no place in *Herpetological Review.*" In no way is my statement simply a personal opinion. It is



a well documented fact which the editor and most readers are well aware of (see Casper, G. 1982. *Biological Extinction*, vol. 1, no. 2, pp. 55-58). "Hampers" is a kind word for a result of legislation which has been directly responsible for severe population declines in many rare species. It is understandable that the FWS does not like to see this embarrassing aspect of federal legislation in print. However, it is unacceptable to censor such information from this or any scientific medium, as Dodd suggests. Dodd is well aware (at least in part) of the factual basis of my statement, for he says in his first paragraph that proposed listings would result in "legions of angry fellow scientists afraid of having their entire research programs wiped out."

Finally, Dodd suggests that I am unlearned and should correct this deficiency before "pontificating about listing being a deterrent to research." Dodd then praises several federally funded wildlife programs, apparently attempting to illustrate how beneficial listing can be. Dodd has misinterpreted my Newsnote as claiming that listing is a deterrent to research, when no such broad criticism was made. The Newsnote mentions an "aspect of listing" which hampers *some* research, especially captive propagation, and then emphasizes the *importance* of another aspect of listing — habitat protection. The positive aspects of listing are well known. For the record, I have worked towards strengthening these provisions, as well as having volunteered hundreds of hours collecting field data for the FWS.

The negative aspects of listing are nevertheless serious and are being increasingly criticized by the zoological community. While several of the programs Dodd mentions are commendable (though often painfully limited to too little and too late), others are undeserving or even harmful, such as recent activities of the FWS Division of Law Enforcement (see Casper, *ibid*). Dodd also mentions programs which for their success have been largely dependent on the expertise developed over several decades by private zooculturists, who are now being forced to give up their researches and species survival programs because of federal listing legislation and regulations.

I would hope that *Herpetological Review* will continue to report both good and bad news in the field of herpetology. Dodd's insupportable objections to basic news reporting are incompatible with mutual government and private efforts towards improving wildlife protection and continuing biological research.

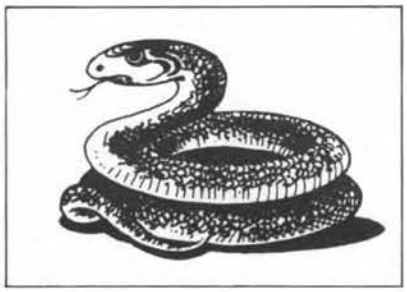
MEETINGS

REPORT ON THE SYMPOSIUM ON "THE STRUCTURE, DEVELOPMENT AND EVOLUTION OF REPTILES" HELD AT THE ZOOLOGICAL SOCIETY OF LONDON ON 26TH AND 27TH MAY, 1983, IN HONOUR OF PROFESSOR A.d'A. BELLAIRS ON THE OCCASION OF HIS RETIREMENT

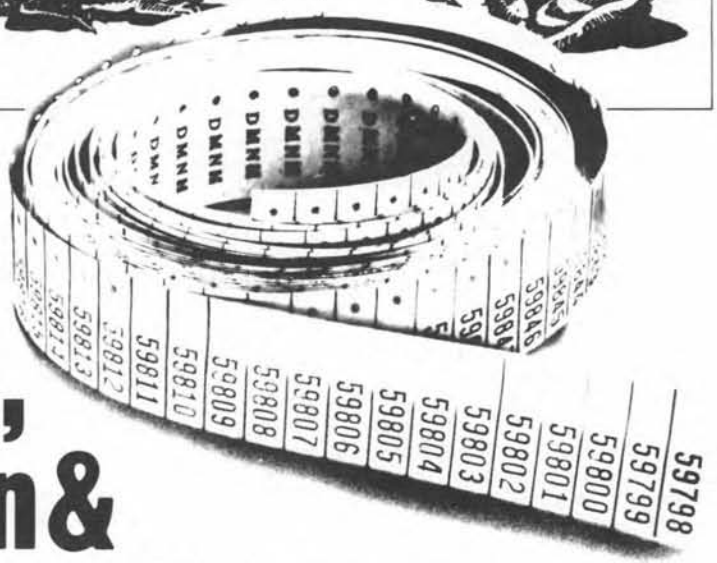
This International Symposium, held under the auspices of The Zoological Society of London, The Anatomical Society of Great Britain and Ireland and The British Herpetological Society, featured 27 speakers from Britain, Australia, Africa, Canada, Holland, Switzerland and the United States of America. The sessions were well attended by delegates from many parts of the world, and all seemed to enjoy the stimulating scientific sessions and the social discussions thereafter.



The contributors were each authorities in their particular field and many were former students, friends or collaborators of Professor Bellairs (St. Mary's Hospital Medical School, London). In part, this determined the nature of the subjects covered, but the latter was also influenced by Professor Bellairs' personal interests and by areas of current investigation in reptile biology. The symposium brought together investigators who are using reptiles in some particular field but who would not normally meet and interact given the somewhat restricted and specialized programmes of many scientific societies and meetings. The presentations were therefore a series of selected highlights in the fields of reptile morphology, development, physiological ecology and evolution. The programme was broad ranging and emphasised the inseparable relationships between form and function, evolution and development, ecology and physiology.

Sometimes investigators with opposing views contributed papers on related topics, e.g. S. V. Bryant (University of California, Irvine) and L. S. Honig (University of Southern California, Los Angeles) on limb development, and M. J. Benton (University of Oxford) and A. J. Charig (Department of Palaeontology, B. M. (N.H.)) on relationships between therapsids and archosaurs during the Triassic, which made for some interesting and lively discussions both during and after the symposium sessions. Many new data were presented and these were often extensive as in the case of G. J. W. Webb (University of New South Wales, Kensington) on sex ratios and survivorship in *Crocodylus johnstoni*, J. P. Loveridge (University of Zimbabwe, Harare) on thermoregulation in *Crocodylus niloticus*, R. A. Avery (University of Bristol) on the control of lizard growth, R. Presley (University College, Cardiff) on the development of the tympanic membrane, and J. M. F. Landsmeer (University of Leiden) on the morphology of the anterior limb in *Varanus*. Professor R. A. Coulson (Louisiana State University, New Orleans) gave an extremely interesting and amusing talk on how metabolic rate and anaerobic glycolysis determine the habits of reptiles, whilst Dr. R. E. H. Reid (Queen's University, Belfast) presented a well balanced account of dinosaur bone histology, illustrated with beautiful photomicrographs. He concluded that few inferences could be drawn about dinosaur endothermy or ectothermy on the basis of bone histology alone. Many new hypotheses were advanced on topics as diverse as: the control of snake epidermal shedding cycles by P. F. A. Maderson (Brooklyn College, City University of New York), the evolution of the long necked chelidae by P. C. H. Pritchard (Florida Audubon Society), the developmental evolution of cartilage and bone by B. K. Hall (Dalhousie University, Halifax), the pathogenesis of cleft lip and palate in reptiles, birds and mammals by M. W. J. Ferguson, the evolution of dental enamel and tooth attachment mechanisms by M. Zeichner-David (University of Southern California, Los Angeles) and J. W. Osborn (University of Alberta, Edmonton) respectively, the endocrinological control of reproduction in male reptiles by V. Lance (Tulane University, New Orleans), the genetic evolution of specialised sex chromosomes by K. W. Jones (University of Edinburgh), skull miniaturization in lizards by O. Rieppel (University Zürich), and the evolution of ornithopod dinosaurs by D. Norman (University of Oxford). Some contributors, e.g. G. L. Underwood (City of London Polytechnic) on the scleral ossicles of lizards, E. N. Arnold (Reptile Section, B. M. (N.H)) on the cloacal and hemipeneal muscles of lizards, and M. J. Benton on the relationships of the diapsidia, had systematic implications. Dr. F. E. Russell (University of Arizona, Tucson) provided a useful summary of snake venoms, whilst Dr. H. R. Bustard (FAO/UNDP Crocodile Breeding Project, India) illustrated the gharial conservation programme in India.

The meeting was a fitting tribute to Angus Bellairs whose interests in reptile biology are widespread and who closed the meeting with some comments on the evolution of snakes, Jacobson's organ and the intermandibular symphysis, as well as more general comments on herpetology and herpetologists. The meeting had opened with an appreciation of Professor Bellairs by the symposium organiser, Dr. Mark Ferguson, who included some anecdotes from Angus Bellairs' wartime and medical school services.



The papers presented at this symposium are being published as a Festschrift in honour of Professor Angus d'A. Bellairs. The volume is entitled "The Structure, Development and Evolution of Reptiles," Editor M. W. J. Ferguson, in the series Symposia of the Zoological Society of London, published by Academic Press. As Number 52, it should be available in March or April 1984.

FEATURES

NOW-IT-CAN-BE-TOLD DEPARTMENT: "WHO THE HELL WAS PERKINS?"

Pregill (*Herp. Review* 14(3):59, 1983) has perpetuated an understandable error on the first name of C. B. Perkins, late Curator of Reptiles at the San Diego Zoo, by referring to him as Cyrus. Perkins abetted this error and named his son, not a herpetologist, Cyrus. C. B. Perkins, as he signed himself, was known to friends and admirers as "Si." The nickname was derived from a character in a comic strip of his childhood, "Si Perkins and His Cat," he once told me.

Laurence M. Klauber (not Lawrence, in loco cit.) relied heavily on Perkins for meticulous editorial work, always acknowledged, and named the leaf-nosed snake *Phyllorhynchus decurtatus perkinsi* after his associate. Perkins, irreverent and self-critical, abhorred patronyms without exception and often protested the honor by remarking, "Some day people will ask, 'Who the hell was Perkins!' "

His full and correct legal name was perhaps one of the best kept secrets in the annals of Western American herpetology. One of the few times it appeared in print was in the Princeton University Yearbook for his Class of 1912. It was Clarence Basil Perkins.

ADDITIONAL NOTES ON COLUBRID SNAKES OF THE GENUS *Tantilla* FROM TROPICAL AMERICA

Information on the systematics of the tropical members of the genus *Tantilla* has been accumulating relatively rapidly recently. A recent account of the genus (Wilson, 1982a) listed 46 species. Since that time, three more, *T. cuesta, T. excubitor,* and *T. tayrae,* have been described (Wilson, 1982b; in press). Subsequent to the preparation and submission for publication of several revisionary papers on various groups of *Tantilla* (Wilson and Meyer, 1971; Wilson, 1976; Wilson and Mena, 1980; Wilson, 1982b; Wilson, in press), various pieces of information about a number of tropical members of the genus have accumulated that merit publication, in the fashion done by Wilson, McCranie, and Porras (1977). This information is presented below.

Tantilla annulata Boettger

This species was recently reviewed by Wilson (1982b). Although the species is known to range at low and moderate elevations (sea level to 850 meters) from extreme southeastern Nicaragua to central Panamá on the Caribbean versant and from Costa Rica to Ecuador on the Pacific (not recorded from Colombia), it has not been reported from the biogeographically important Península de Osa of southwestern Costa Rica.

I have had the opportunity, through the courtesy of Roy W. McDiarmid and Joan Dudley, to examine two specimens of this species, collected by McDiarmid, from this area. One specimen (USNM 219604) was found on 7 July 1973 under a log in the forest at 60 meters elevation at the Osa Tropical Science Center, ca. 6.25 km SW Rincón de Osa, Prov. Puntarenas. The other (USNM 219605) was found on 13 July 1973 within the grounds of the Center as well, ca. 2.5 km SW Rincón de Osa. It was dug up by a bulldozer behind the hangar near the air field at 30 meters elevation.

Data on scutellation and color pattern for these two male examples agree well with that presented by Wilson (1982b) for Costa Rican *T. annulata.* Wilson (1982b) noted, however, that Costa Rican specimens have fewer average ventrals and subcaudals in both sexes than do those from Panamá. The subcaudal count for USNM 219604 (64) is two scales above the higher range value (62) for Costa Rican males and falls within that (61-65) for Panamanian males. The ventral count for USNM 219605 (148) is also two scales above the higher range value (146) for Costa Rican males and, similarly, lies within the range (147-151) for Panamanian males. The Osa Peninsula lies between the localities for most Costa Rican specimens and those for Panamanian specimens.

Tantilla jani (Günther)

I have been able to examine, through the courtesy of Robert L. Seib, a specimen of *Tantilla jani* that represents an elevational record for the species. Wilson (1982b) gave the elevational range of this species as "ca. 305-609 m," which, thus, barely established the species as occurring at moderate elevations (600-1500 meters) along the Pacific versant from eastern Oaxaca, México to south-central Guatemala. On 24 August 1982 Seib collected a single male specimen of *T. jani* (MVZ 177109) at Finca Monte Perla, 18.8 km NE (by road) of Cacaohatán [=Cacahoatán or Cacahuatán], Chiapas, México. The specimen came from an elevation of 960 meters, well within the Subtropical Wet Forest formation of Holdridge (1967), 351 meters above the previously-known highest elevation.

The specimen agrees in essential respects with the description given by Wilson and Meyer (1971), except that the middorsal pale stripe is comparatively muted, consisting of discrete basal spots only slightly paler than the surrounding ground color. The pale lateral stripe is similarly poorly distinguished. The ventral color in life was described as "pale greenish."

Tantilla lempira Wilson and Mena

Wilson and Mena (1980) described *Tantilla lempira* on the basis of three specimens from the upland pine *(Pinus oocarpa)* forests of south-central Honduras. Wilson (1982b) reported on an additional specimen from near the type locality (3.7 km N Zambrano, Depto. Francisco Morazán). Herein I report on one additional specimen from the type locality and a second from another locality at a higher elevation than previously known and from a different vegetation type.

The additional specimen from the type locality was collected by H. E. Lawler and L. Porras on 29 January 1980. This male specimen (LSUMZ 38833) has 138 ventrals and 52 subcaudals. All other scutellational features are in agreement with those of the type series. The specimen appears to be an adult and has a total length of 244 mm, a tail length of 58, and a relative tail length of 0.238.

The second specimen (NSU 5236) was collected at Agua Fria at the crest of the road from La Paz to Tutule over the Cordillera de Montecillos, elevation 1730 meters, Depto. La Paz by K. L. Williams and L. D. Wilson on 26 July 1980. The specimen came from beneath a pine log on a slope in a recently cut-over pasture. The undisturbed vegetation is *Pinus pseudostrobus* forest (Lower Montane Wet Forest formation of Holdridge, 1967). The elevation from which this specimen came is 280 meters higher than that of the type locality and in a different vegetation zone. Thus, the range of *T. lempira* extends into the *pinabetes* (= pineland cloud forest). The specimen is a juvenile female with the following characteristics: ventrals, 154; subcaudals, 44; total length, 111 mm; tail length, 18 mm; relative tail length, 0.162; umbilicus on ventrals 123-124.

Six specimens of *Tantilla lempira* are now known from three departments (El Paraiso, Francisco Morazán, and La Paz) in Honduras. The species is known to range from moderate to intermediate elevations of both versants of central Honduras. Two males have 138-143 ventrals ($\bar{x}$ = 140.5), 49-52 subcaudals ($\bar{x}$ = 50.5), and 190-192 ventrals + subcaudals ($\bar{x}$ = 191.0). Four females have 148-154 ventrals ($\bar{x}$ = 151.3), 36-44 subcaudals ($\bar{x}$ = 40.0), and 186-198 ventrals + subcaudals ($\bar{x}$ = 191.3).

Tantilla melanocephala (Linnaeus)

Wilson and Mena (1980) summarized information on the distribution of *Tantilla melanocephala* (pattern type A in their terminology) in Honduras. All specimens listed by them came from the Pacific versant of the country, with the exception of one from Pataste, Depto. Olancho, in or near the Guayape-Guayambre river valley.

Through the courtesy of Harold A. Dundee, I examined a specimen of this snake collected by him S of Villa de San Antonio, Depto. Comayagua. This specimen (TU 19749) represents the first specimen from the arid Comayagua Valley and the second of this otherwise Pacific versant form from the Caribbean versant.

The color pattern and scutellation of the specimen are typical for pattern type A.

Tantilla nigra (Boulenger)

Tantilla nigra remains known only from the holotype (BMNH 1946.1.8.69). It was described by Boulenger (1914) from a hill or ridge called Peña Lisa, near Condoto (5° 06'N, 76° 37'W), Depto. Chocó, Colombia. Recently, through the courtesy of Donald E. Hahn and A. F. Stimson, I received a description of the holotype and herein point out an error in the counts of ventrals and subcaudals. Boulenger (1914) gave counts of 143 and 63, respectively; counts provided by Hahn and Stimson (using the Dowling method to count ventrals) are 137 and 64. Boulenger's (1914) description is otherwise accurate.

Tantilla schistosa (Bocourt)

Wilson (1982b) recently revised this species on the basis of the study of 40 specimens from the length of the range extending from Oaxaca and Veracruz, México to Panamá. Some areas within the range are better represented than others. I have had the chance, through the courtesy of Edmond V. Malnate, to examine three additional specimens of this species, two from Guatemala and one from Honduras, from which areas Wilson (1982b) saw 9 and 1 specimens, respectively.

The second Honduran specimen (ANSP 28714) was collected 10-15 km W Yorito, Depto. Yoro in the approximate vicinity of the point of collection (Portillo Grande) of the other known specimen. ANSP 28714 is a male with 125½ ventrals and 39 subcaudals. These data conform to the pattern discerned by Wilson (1982b) with regard to ventrals but not subcaudals. He noted that relatively low numbers of ventrals (121-122 in males) exist in Guatemalan, Honduran, and southwestern Costa Rican specimens, as opposed to the remainder of the range (129-144). He also indicated that relatively low numbers of subcaudals (24-33) obtain in Belize, Honduras, Nicaragua, and Panamá. However, the count for ANSP 28714 falls within the higher range (33-42) for specimens from México and Guatemala.

The two Guatemalan specimens (ANSP 28712-13) are from Finca Volcán, Depto. Alta Verapaz and the data on ventrals (124 in male ANSP 28712 and 127 in female ANSP 28713) conforms to the above-mentioned pattern, as do the subcaudals counts (41 and 33, respectively).

Tantilla semicincta (Duméril, Bibron, and Duméril)

In his review of *Tantilla semicincta*, Wilson (1976) noted several differences between material of this species from Colombia and that from Venezuela. However, he had available only a single specimen from the latter country. I have recently had the opportunity to examine another Venezuelan specimen (UF/FSM 42350) from Punta Cardón on the Península de Paraguana in Est. Falcón. This specimen is similar in pattern to the one (USNM 107324) reported by Wilson (1976), but also resembles, to some extent, material from Colombia and acts to weaken somewhat the distinctions he noted between Colombian and Venezuelan material of the banded phase of this dichromatic species. The UF/FSM specimen has 14 black body bands and 7 on the tail (counted on the left hand side of the body). The black body bands are separated by pale bands ranging from 3 to 5 scales in length. The black bands on the body extend laterally to the upper half of the first dorsal scale row. The dark head cap is poorly distinguished from the pale nuchal band and does not extend posterolaterally onto the temporals or posterior supralabials (cf. fig. 3 in Wilson, 1976). The pale nuchal band extends on the midline from the posterior one-third of the parietals to the first middorsal scale.

In comparing Colombian material of *T. semicincta* to the single Venezuelan specimen available to him, Wilson (1976) stated that "USNM 107324 has well-defined dark crossbands . . . that are separated by pale bands about six scales in length (1 to 3 in Colombian specimens). The number of dark tail bands is 3, which is much lower than the number in Colombian specimens (4-13, $\bar{x}$ = 9.1). Also, the nuchal band is longer, occupying half of the parietals and one and one-half dorsal scales (as opposed to a maximum size of one-third of the parietals and one dorsal scale in Colombian specimens)." As mentioned above, these distinctions are somewhat muted by consideration of the characteristics of UF/FSM 42350. The length of the pale bands (3 to 5 scales) is intermediate, the number of dark tail bands falls within the range for Colombian material, and the length of the pale nuchal band is equivalent to the maximum condition seen in Colombian material. Although Wilson (1976) did not mention the fact, the dark body band count for USNM 107324 is 12, one lower than the lowest count for banded Colombian material. The band count for UF/FSM 42350 falls within the range for Colombian material.

In light of the intermediacy of pattern characteristics of UF/FSM 42350, it is of interest to note that the specimen is also from an intermediate locality (the Península de Paraguana) between those in Colombia and that for USNM 107324 (Caracas). It seems likely, therefore, that when additional material of this species from coastal Venezuela becomes available that the pattern conditions of material from Colombia and Venezuela will be shown to grade into one another and that the hesitance of Wilson (1976) to recognize the distinctions nomenclaturally was justified.

I have also examined another two specimens of this species (AMNH 109843-44), brought to my attention by Charles W. Myers, that are from Santa Marta, Depto. Magdalena, Colombia. Scutellational data for these two females fall within ranges published by Wilson (1976). Both are of the banded phase.

Tantilla taeniata (Bocourt)

Almost every specimen of *Tantilla taeniata* collected proves to provide new insights into the systematics of this as yet poorly-understood snake. UF/FSM 53616 is no exception. This specimen was collected at Santa Rosa, 1260 m elevation, Chiapas México and provides a new record for the state. In addition, this example helps to bridge the gap between the populations in Oaxaca and those in Guatemala (presently of unknown provenance within the country) (Wilson, 1982b). The elevation is the highest known for the species (previous upper limit, 1000 m - Wilson, 1982b).

The ventral count of 164 for this male specimen is 7 scales above the previous known upper limit for males; the subcaudal count of 71 is 4 scales above. The total underbody scale count of 235 is 18 scales above the previous limit.

The color pattern is typical for the species (Wilson and Meyer, 1971), except that the pale nuchal band is divided middorsally, as is the case with a few other known specimens.

Tantilla tayrae Wilson

This species was recently described by Wilson (in press) from a locality at a moderate elevation (760 m) on the slopes of Volcan Tacaná in Chiapas, México. The hypodigm consists of five specimens, four males and one female. The species was allocated to the *taeniata* section of the *taeniata* group and was thought to be most closely related to the also recently-described *Tantilla cuesta* (Wilson, 1982b).

In August of 1982 Robert L. Seib collected four additional specimens of *T. tayrae*. One specimen (MVZ 177105) is from the type locality and the other three are from a new locality nearby. These latter specimens (MVZ 177106-08) came from Finca Monte Perla, 1818 km NE (by road) Cacaohatán [= Cacahoatán or Cacahuatán], Chiapas, México. All three of these specimens came from an elevation of 960 meters.

The type series of *T. tayrae* exhibited a preponderance of males; the new series consists of three females and one male. One of the females is a juvenile. Much of the data on scutellation are in agreement with those of the type series. The ventral counts for the three females are 146½, 150½, and 154½ (all have half ventrals preceding the anal plate); for the male the figure is 143. Subcaudal counts for females are 47, 47, and 51. The known overall range in ventrals for male *T. tayrae* is 140-144 ($\bar{x}$ = 142.2) and for females 146-154 ($\bar{x}$ = 149.0). Subcaudals range from 46-49 ($\bar{x}$ = 47.2) in males and 44-51 ($\bar{x}$ = 47.3) in females. Ventral plus subcaudal figures range from 186-193 ($\bar{x}$ = 189.4) in males and from 190-201 ($\bar{x}$ = 196.3) in females.

The color and pattern of the four new specimens are in close agreement with that of some members of the hypodigm (see Wilson, in press, for a discussion of pattern variation). As noted by Wilson (in press), *T. tayrae* is unusual in exhibiting variation in diagnostic pattern characteristics.

Tantilla vermiformis (Hallowell)

Our knowledge of *Tantilla vermiformis* was recently summarized by Van Devender and Cole (1977) and Wilson (1982b). Wilson (1982b) mapped the known range of this species, which is composed of two populational segments, one around Lake Managua in Nicaragua and the other in the vicinity of Cañas and Los Angeles de Tilarán in northwestern Costa Rica. Recently, Wayne Van Devender brought to my attention the existence of another specimen from Costa Rica that helps to fill in the gap in the range between these two segments. The specimen (RWV 1330) was collected at the Santa Rosa National Park administration building within the park located in Prov. Guanacaste about 20 km S of the Nicaraguan border. The snake

was brought out by a fire that occurred in May of 1976.

The specimen is a female with 123 ventrals and 20 subcaudals and with the primary temporal not fused to the sixth supralabial. All these data fall within ranges seen in other Costa Rican material, although the last character is more typical of Nicaraguan specimens.

ACKNOWLEDGMENTS

I would like to thank a number of individuals for keeping me alerted concerning the accretion of noteworthy material of this genus; they are W. Ronald Heyer, Roy W. McDiarmid, Peter Meylan, Charles W. Myers, Robert L. Seib, and R. Wayne Van Devender. I am also grateful to Howard Lawler, Louis Porras, and Kenneth L. Williams for permission to report on specimens collected during field work in Honduras.

AGGRESSION BETWEEN TWO *Drymarchon corais melanurus* IN CAMPECHE, MEXICO

Field observations of combat between snakes are rare and open to various interpretations. In the older literature, ritualized combat was often viewed as a territorial dispute between males, but since territorial defense has not been observed for any snake this interpretation is only speculative. Observations of combat in which the sexes of the individuals were not determined have sometimes been interpreted as courtship. Shaw (1951) suggested that homosexual behavior of one male directed toward another could initiate combat. In most cases, combatants do not bite or inflict damage on each other (Bogert and Roth. 1966), but Leloup (1964) indicated that combat between mambas *(Dendroaspis polylepis)* after being fed in captivity resulted in the occasional injury or death of one individual. Many of the observations of biting have been made on captive individuals and occurred soon after a feeding bout.

On 7 December 1974, one of us (Waide) observed two *Drymarchon corais melanurus* in the archeological ruins of Chicanna, 7 km west of Xpujil in southeastern Campeche, Mexico. Each individual had a firm grip on the other directly behind the head, and considerable blood was flowing from each wound (see Fig.). The snakes were first seen at about 1600 and observed at intervals thereafter for about 2.5 hours. During this period they moved less than 5 m and maintained their hold on one another. They demonstrated none of the entwining of bodies or ritualized movements characteristic of what has been called territorial combat, although their bodies occasionally overlapped. Each snake was approximately 2 m in length, but they could not be observed closely enough to ascertain sex. The last observation occurred just after dark when the two individuals were stretched out head to head with their tails pointing in opposite directions. One snake appeared to be ingesting the other, but light conditions were very poor and this observation is far from certain. At 0600 the next morning both snakes were gone.

Tinkle (1951) reported biting between two individuals of *Drymarchon corais couperi x melanurus* during courtship. Biting and releasing behavior by the male escalated to the point that damage was being inflicted. Although they were forcibly separated, the female later died, apparently of injuries received. That the activity Tinkle observed occurred in captivity and between individuals of different subspecies might call into doubt whether such behavior could occur in nature. Gillingham and Chambers (1980) observed no biting in four courtship episodes of a pair of *D.c. couperi* in captivity. Biting during courtship has been documented for other groups (*Elaphe;* Gillingham, 1979), but it is rarely of the violent nature described by Tinkle.

Aggression between conspecifics also occurs as the result of a mutual feeding response. Snakes that have been stimulated by the presence of prey occasionally attack other individuals in the same cage (Leloup 1964). Two Eastern garter snakes *(Thamnophis sirtalis)* observed feeding on the same frog in the field attempted to ingest one another upon disposing of the prey (Gillingham, pers. comm.).

If the observed aggressive encounter were initiated during courtship or as a mutual feeding response, the damage done to each individual indicates an escalation of aggression not generally associated with such activities. The lack of data on the sex and the history of the two individuals immediately prior to their encounter makes interpretation of the observation difficult. The ophiophagous nature of *Drymarchon* suggests that a mutual feeding response is a more likely explanation. In either case, the observation we report indicates that conspecific aggression to the point of severe injury does occur in nature, even though the motivation for this particular incident must remain obscure.

ANNOUNCES

A new book of major importance to ECOLOGISTS • SYSTEMATISTS • HERPETOLOGISTS
ICHTHYOLOGISTS • MAMMALOGISTS • CONSERVATIONISTS • UNIVERSITY RESEARCHERS

VERTEBRATE ECOLOGY AND SYSTEMATICS . . . A TRIBUTE TO HENRY S. FITCH

Special Publication No. 10

Edited by RICHARD A. SEIGEL, LAWRENCE E. HUNT, JAMES L. KNIGHT, LUIS MALARET and NANCY L. ZUSCHLAG

Twenty-four international authorities provide a comprehensive tribute to the natural historian whose outstanding studies have provided the foundation for much of modern ecology.

About 200 pages, with 75 figures, 89 tables and 2 appendices plus index. ISBN 0-89338-019-0. 7 x 10 inches, paperbound.

—CONTENTS—

- **PART I. Introduction**

DUELLMAN Henry S. Fitch in perspective.
V. FITCH A bibliography of Henry S. Fitch.

- **Part II. Reproductive Biology and Population Dynamics**

BROWN & PARKER Growth, reproduction and demography of the racer, *Coluber constrictor mormon,* in northern Utah.
PLATT Growth of bullsnakes *(Pituophis melanoleucus)* on a sand prairie in south central Kansas.
GREGORY Communal denning in snakes.
SEIGEL Parameters of two populations of diamondback terrapins *(Malaclemys terrapin)* on the Atlantic Coast of Florida.
BURKETT An ecological study of the cricket frog, *Acris crepitans.*
PLUMMER Female reproduction in an Arkansas population of rough green snakes *(Opheodrys aestivus).*
RAND Clutch size in *Iguana iguana* in central Panama.
HALL & MULHERN Are anuran amphibians heavy metal collectors?

- **Part III. Feeding and Behavior**

ANDREWS Energetics of sit-and-wait and widely-searching lizard predators.
GREENE Feeding behavior and diet of the eastern coral snake, *Micrurus fulvius.*
VON ACHEN & RAKESTRAW The role of chemoreception in the prey selection of neonate reptiles.
SHINE Ecology of small fossorial Australian snakes of the genera *Neelaps* and *Simoselaps* (Serpentes, Elapidae).
HENDERSON *Scaphiodontophis* (Serpentes: Colubridae): A natural history and a test of a mimicry-related hypothesis.
CARPENTER Dominance in snakes.
J. FITCH An experimental study of the variation in habitat selection and occurrence of the deermouse, *Peromyscus maniculatus gracilis.*

- **Part IV. Systematics and Biogeography**

WEBB Herpetogeography in the Mazatlan-Durango region of the Sierra Madre Occidental, Mexico.
ECHELLE et al. Systematic review of the percid fish, *Etheostoma lepidum.*
WILLIAMS & DUELLMAN *Anolis fitchi,* a new species of the *Anolis aequatorialis* group from Ecuador and Colombia.

LEGISLATIVE ALERT

AMERICAN ALLIGATOR RECLASSIFIED IN TEXAS

The American alligator *(Alligator mississippiensis)* has been reclassified under provisions of the Endangered Species Act of 1973 from a status of Threatened or Endangered to Threatened by Similarity of Appearance. The reclassification was published in the *Federal Register* on October 12, 1983, and became effective November 14. The change in status is based on evidence that the alligator is no longer biologically endangered or threatened within the State of Texas and brings the Federal classification in line with neighboring Louisiana. As such, the State of Texas may now institute comprehensive management plans for alligators which could include harvesting of the species in accordance with State laws. While Federal permits are no longer required for scientific or commercial activities within the State, the exportation of parts and products of Texas alligators is still controlled through the provisions of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES). Copies of the *Federal Register* document outlining the reclassification and detailing the basis for this action may be obtained by writing Mr. David Bowman, U.S. Fish and Wildlife Service, P.O. Box 1306, Albuquerque, New Mexico 87103, U.S.A. ●

PINE BARRENS TREEFROG DELISTED IN FLORIDA

The U.S. Fish and Wildlife Service recently published a final rule in the *Federal Register* (November 22, 1983) delisting the Florida population of the Pine Barrens treefrog. The frog was listed as Endangered in 1977 when information was provided to the Service that only 7 populations remained and that there was the potential of habitat destruction to these populations. After the species was listed, surveys were conducted in Florida by Paul Moler and in Alabama by Robert Mount in order to better understand the biological requirements of the treefrog preliminary to the development of a conservation plan. As a result of these studies, the frog was found to be more widely distributed than originally believed and there are presently over 150 populations known, many of which are on Federal or State lands. Delisting removes all Federal restrictions regarding the species although it remains protected in Florida by State law. Copies of the *Federal Register* document delisting this population can be obtained by writing Dr. Michael Bentzien, U.S. Fish and Wildlife Service, 2747 Art Museum Drive, Jacksonville, Florida 32207, U.S.A. ●

SOCIETIES

THS OFFERS *HERPETOLOGY IN OHIO — FIFTY YEARS AGO*

The Toledo Herpetological Society is pleased to offer for sale a 64-page booklet by Roger Conant titled *Herpetology in Ohio — Fifty Years Ago.* This wonderful little book relates the entertaining and often humorous stories about Dr. Conant's experiences while collecting reptiles for his classic work *The Reptiles of Ohio.*

> Dr. Conant's eloquent personality is reflected throughout the text and his ability to write simply and succinctly provides pleasant reading. The matter-of-fact style and personable manner deludes the reader to believe he has received a personal correspondence from the author.

BRITISH HERPETOLOGICAL SOCIETY MEETINGS 1984

The meetings are held in the Lecture Theatre of the Linnean Society of London, Burlington House, Piccadilly, London W1 and start at 7.00 pm unless indicated otherwise. As always, SSAR members passing through London are most welcome.

FEBRUARY 29th
Mr. Brian Banks (Biological Sciences, University of Sussex): Breeding ecology of the natterjack in Britain in relation to conservation.

MARCH 13th
Annual General Meeting followed by Dr. Alan Charig (Chief Curator of Fossil Amphibians, Reptiles and Birds, Department of Palaeontology, British Museum (Natural History), London): Dinosaurs: myths and misconceptions. Mention will be made of the Surrey Dinosaur.

APRIL 25th
Dr. J. Riley (Department of Biological Sciences, University of Dundee): Relationship of parasitic pentastomid behaviour with reptiles. Reptiles can be infested by 'lungworms'.

MAY 17th
Mr. C. A. Snell (Greenwich Nature Conservation Society): Garden breeding and a wasteland reserve for herpetofauna in SE London.

JUNE 20th
Amphibia and Reptiles Worldwide. A discussion on care and breeding organized by the Captive Breeding Committee. Members are encouraged to bring live animals, preserved specimens and 35 mm slides for display and to illustrate discussions.

SEPTEMBER 29th
A joint Saturday meeting (date to be confirmed). A colloquium on amphibian and reptile husbandry organized by the Captive Breeding Committee (details in *BHS Bulletin* later).

OCTOBER 26th
Mr. C. J. Raxworthy (Department of Zoology, Bedford and Royal Holloway Colleges, University of London, Egham, Surrey): Herpetofauna of SW Morocco - results of a University of London Union Natural History Society Expedition 1983.

NOVEMBER 21st
Mr. M. P. Simmonds (Department of Zoology, Westfield College, University of London): Ecology of the feral African clawed toad *(Xenopus laevis)* in Britain. ●

THE FIRST MALCOLM SMITH DINNER OF THE BRITISH HERPETOLOGICAL SOCIETY

Hosted by the President of the British Herpetological Society, the Earl of Cranbrook, the first Malcolm Smith Dinner was held on Friday, 16th December 1983 in the Peers' Dining Room, House of Lords, Westminster. The event was so named after the Society's founding president, Dr. Malcolm Smith, author of the *Fauna of British India, including Ceylon and Burma*, Vols. I-III (reptiles) and the standard textbook for many years on British herpetofauna. Primarily a social event, the President's personal guests were Dr. R. F. Inger (President of the Herpetologists' League) and Mrs. Inger, and Miss A. G. C. Grandison (Head of the Amphibian Section, British Museum (Natural History), London). Other guests (BHS members) included Dr. R. A. Avery, Prof. A. d'A. Bellairs, Dr. H. R. Bustard, Mr. K. F. Corbett, Dr. J. F. D. Frazer, Dr. S. P. Gittins, Prof. G. A. D. Haslewood, Dr. K. G. Klemmer, Dr. M. R. K. Lambert (Chairman of the Society), Mr. T. E. S. Langton, Mr. J. Pickett, Dr. I. R. Swingland and Mr. V. F. Taylor. Before the dinner, Lord Cranbrook took his guests on a brief tour of the House of Lords showing where the Queen presides over the Opening of Parliament and the main room in the Lords (the Commons having declined) where President Reagan gave his historical address to the two Houses in 1982. After a reception, the 30 diners in all sat comfortably at either side of a long central table in the Peers' Dining Room with its splendidly gothic decor.

After toasting the Queen and the British Herpetological Society at the end of the dinner, Lord Cranbrook then gave a Presidential Address to the Society (an Abstract of this Address will appear in the *BHS Bulletin*). Dr. Inger briefly replied in his capacity as President of the Herpetologists' League outlining his shared experiences with Lord Cranbrook when working with him in Malaysia.

The function was much enjoyed by partici-

pants with the hopes that it would be repeated and the occasion was recorded under 'Dinners' in the 'Court and Social' of *The Times* the following day. Apart from being a social event, it is hoped that the Dinner will help to establish herpetology as a notable discipline in Britain (and for that matter elsewhere), as certainly enjoyed by entomology and ornithology as well as by mammalogy.

GEORGIA HERPETOLOGICAL SOCIETY

The Georgia Herpetological Society has been defunct since 1981. Very few members remain from the original GHS. Key members have moved and a case of 'burn-out' occurred among the remaining few. However, there is a strong nucleus of advanced and amateur herpetologists in the Atlanta area. A meeting was held in October to restructure and reorganize the GHS.

The state of Georgia needs an active and viable herp society and we plan of offer such. It will take time and a great effort for us to get back to where we were in the mid 70's. The GHS hopes to publish a bulletin and would like to exchange with other societies as in the past. Wish us luck, we'll need it.

THE BRITISH HERPETOLOGICAL SOCIETY

The British Herpetological Society was founded in 1947 with the broad aim of catering for all aspects of interest in reptiles and amphibians. Initiated by a small number of enthusiastic and well-known naturalists, including the first president and author of the standard textbook on British herpetofauna, Dr. Malcolm Smith, the Society expanded rapidly and today enjoys national status with many international connections.

Publications

British Journal of Herpetology, published bi-annually, contains papers of original research in herpetology.

British Herpetological Society Bulletin, published bi-annually, contains notices, news items, articles and original papers on all aspects of herpetology.

The Care and Breeding of Captive Reptiles, a book with papers on recent developments in breeding reptiles in captivity. Available to members at a reduced price of £3.00 + £0.50p postage. Purchase orders to the Chairman of the Captive Breeding Committee.

Conserving Sea Turtles by N. Mrosovsky. £5.00 + £0.75p postage and packing.

British Journal of Herpetology Vol. 1, a hardcover bound facsimile reprint. £10.00 + £1.00 postage and packing.

Information Sheets are produced on the care of reptiles and amphibians in captivity. These are continuously added to and updated, and include one on establishing Crested Newts in garden ponds.

Subscriptions

Ordinary members £10. Junior members £3. Institutions and Libraries £17.

All subscriptions become due on the first day of January each year. Members joining after 31 August may pay an additional £5 to receive the previous half's publications; otherwise membership will commence 1 January of the following year. Send to:

The Membership Secretary
The British Herpetological Society
c/o Zoological Society of London
Regent's Park
London NW1 4RY, U.K.

NEWSNOTES

CURATORIAL ASSOCIATE POSITION IN HERPETOLOGY

Full-time curatorial associate position in Herpetology will be available in the near future (March-April). Due to short deadline for notice, further details for the position have yet to be negotiated. Position collection management oriented. Interested individuals should contact and/or send curriculum vitae to: Dr. Pere Alberch, Museum of Comparative Zoology, Harvard University Cambridge, Massachusetts 02138; phone: (617) 495-2496, after Feb. 1, 1984.

SPACE AVAILABLE AT USFW REFUGE IN PUERTO RICO

THE U.S. FISH AND WILDLIFE SERVICE has space available at the Cabo Rojo National Wildlife Refuge for institutions or research groups interested in establishing an environmental field station in Puerto Rico. The Cabo Rojo NWR encompasses 587 acres of land in the semi-arid southwest and has a 42-room building. The site is close to salt flats, mangroves, shallow bays and reefs, and is within 15 mi of the Univ. of Puerto Rico, UPR Agricultural Experiment Station, UPR Marine Laboratories, 3 Commonwealth Forests and 1 Commonwealth Wildlife Area. One endangered species, the Yellow-shouldered Blackbird , is found at Cabo Rojo. For further information on the use of Cabo Rojo NWR write to SEAN FURNISS, Refuge Manager, Caribbean Islands NWR, P.O. Box 510, Boqueron, PR 00622-0510.

TURTLE TRADE DATA NEEDED

The U.S. Fish and Wildlife Service needs information on trade in adults and hatchlings of the flattened musk turtle, *Sternotherus depressus*, and the yellow-blotched sawback, *Graptemys flavimaculata*. We specifically need to know the prices that are being asked for these species and the sources of supply. Should anyone be able to assist, please contact either Mr. John Pulliam, U.S. Fish and Wildlife Service, 300 Woodrow Wilson Drive, Suite 3185, Jackson, MS 39213 or Dr. C. Kenneth Dodd Jr., Office of Endangered Species, U.S. Fish and Wildlife Service, Washington, D.C. 20240. These data are needed to assess the threat to these species from trade.

TURTLE TAGGING AT TORTUGUERO

The New York Zoological Society is sponsoring a sea turtle research program at Tortuguero National Park in Costa Rica. The program supports and augments sea turtle research sponsored by the Caribbean Conservation Corporation and is directed by Professor Archie Carr of the University of Florida. Departures from Miami are tentatively scheduled for July 13, July 27, August 10 and August 24. Each tour will be of 18 days duration, including four days in transit. For further information, contact:

John Behler, Curator of Herpetology
New York Zoological Society
185th Street and Southern Boulevard
Bronx, New York 10460, U.S.A.

GRANTS FOR WILDLIFE REHABILITATION

The Honors, Awards and Grants Committee of The National Wildlife Rehabilitation Association would like to announce the initiation of a small grants program. We expect $1000.00 to be available beginning July 1, 1984 which could be used to support a single $1000.00 project or several smaller projects that add up to $1000.00, depending on the qualifications of applicant. Funds will be available for a project in the field of wildlife rehabilitation *only*, applicants must demonstrate financial need, and applicants must submit a typewritten proposal which includes name(s) and resumé of personnel involved, objective of the project, a brief statement of literature review, a brief description of how the work will be carried out, and an itemized budget. An annual report on progress will be required.

The committee has also established three awards as follows:

Lifetime Achievement Award — This would go to an individual whose primary identification is that of a wildlife rehabilitator who has contributed to the field in a major way for many years. The awardee will receive a plaque, $100.00 and free conference registration. The award will be presented at the conference.

Significant Achievement Award — This would be to a person who has contributed something of significant merit to the field of wildlife rehabilitation within the last 2 years. Contribution can be a research finding, publication,

organization of a program, etc., as long as the major theme is that of wildlife rehabilitation. The awardee would receive the same benefits as for the Lifetime Achievement Award.

Keynote Award — This award would pay travel and lodging expenses for one keynote speaker for each annual conference. The speaker would be selected by the host committee for the annual conference.

Suggestions of individuals who might be appropriate awardees and proposals for grants should be submitted to:

Dr. G. E. Duke

PRICE INCREASE FOR BACK ISSUES OF *HERPETOLOGICA*

The Board of Trustees of the Herpetologists' League has voted to substantially increase the cost of back issues of *Herpetologica*, starting 1 January 1985. The exact increment will be determined this summer. Current prices are listed in *Herpetologica* 34(3):322. Address inquiries and orders to:

W. Ronald Heyer, Publications Secretary
The Herpetologists' League
Division of Amphibians and Reptiles
Natural History Building

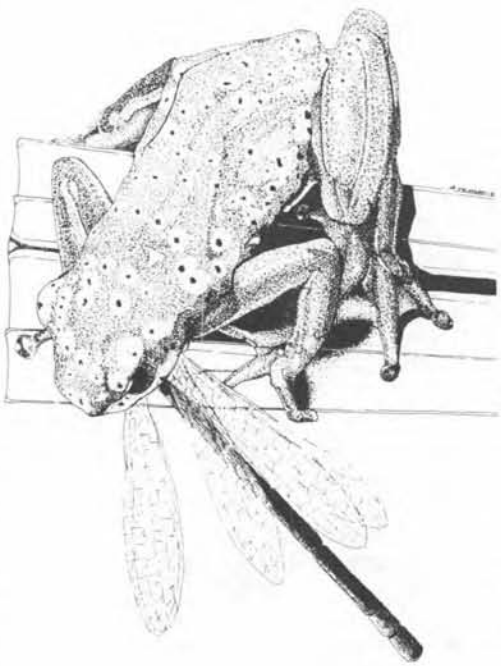
BLANCHARD PAPERS AVAILABLE

A number of published works of Frank N. Blanchard are available in limited quantity. All items, both bound and unbound, are in new condition.

There are *three* complete sets of his papers, each bound in two cloth-bound volumes. In addition to his papers, they include the biographical in memoriams about him. There is one cloth-bound volume of his collected papers, including all except the three long ones and the biographies.

In addition to the above sets, there are *two* cloth-bound copies of *A Key to the Snakes of the United States, Canada and Lower California*. Published as vol. 4, pt. II of Papers of the Michigan Academy of Science, Arts and Letters, 1925. 65 pages. And there is *one* copy of the same title published separately in 1939 with paper cover.

Also available are *two* copies of *A Revision of the King Snakes: Genus Lampropeltis*. Smithsonian Institution, Bulletin 114, 1921, 260 pages, paper cover.



Also available are paper separates by Frank N. Blanchard. There are 38 titles, some with more than one copy. They range from 1-17 pages. If you are interested in purchasing any of the above, please make offers.

7559 Second Street
Dexter, Michigan 48130 ●

NEW SOURCE OF WATERPROOF LABELS

In the process of curating a vertebrate museum one is always in need of chemical resistant waterproof labels. Traditionally these labels have been composed of 100% rag bond. Such paper is expensive and often difficult to obtain. I began a search for an effective alternative and found Nalgene "Poly-Paper" (Catalogue #6304-0811) used in combination with the Minolta EP 310 copier to be an adequate substitute. I stored the labels prepared by this manner in the following solutions: 95% Ethyl alcohol; 50% Isopropyl alcohol; 99% Isopropyl alcohol; 10% Formaldehyde; 37% Formaldehyde and distilled water. In none of the solutions did any fading or bleeding of the print occur during one year storage nor was there any destruction of the paper. I can recommend the above combination as an easy available source for personalized labels.

James D. Lane, Department of Biological & Environmental Sciences, McNeese State University, Lake Charles, Louisiana 70609, U.S.A. ●

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoo, Box 6040, Knoxville, Tennessee 33719.

COURTSHIP AND COPULATION IN THE TIMOR MONITOR, *Varanus timorensis*

Until recently, there have been few detailed descriptions of varanid courtship behavior (Carpenter and Ferguson, 1977). Courtship behavior has now been described in *Varanus komodoensis* (Auffenberg, 1978, 1981b). In this paper I describe courtship and copulation in a pair of captive Timor monitors *V. timorensis*.

MATERIALS AND METHODS

A pair of adult *V. timorensis* were secured from a dealer in September 1980. The male measured 19.5 cm snout-vent length (SVL) and 51.5 cm total length (TL) and the female 18.0 cm SVL and 46.5 cm TL. They were housed in a glass-fronted enclosure measuring 95 X 50 X 72 cm. The floor was covered with wood shavings, and two pieces of bark were provided for hiding. A single 75 W reflector lamp provided heat and light. The photoperiod was 12L:12D. The lizards were fed small laboratory mice, crickets, and canned dog food. Water was provided in a shallow container.

Courtship and copulation occurred frequently between 9 and 20 February 1981. Videotaping was sequenced intermittently during this time, and the descriptions presented here are based on analysis of the sequences. One sequence was selected for descriptive and temporal analysis. This was time-dated subsequent to the actual activity, so the sequence begins at 00:00:00. A second period of courtship activity occurred roughly 10 months later between 15 and 28 December 1981. Acts and act systems observed were similar to those recorded earlier.

OBSERVATIONS

For analysis and description the behavior was divided into three phases: courtship approach, courtship, and copulation.

PHASE I. COURTSHIP APPROACH. This was the shortest of the three phases, lasting 5 to 7 s. The male approached caudally and/or laterally, straddled the female and moved forward. Tongue flicking occurred as he moved. I considered this phase terminated when the male's snout was above the female's snout and he was straddling her.

PHASE II. COURTSHIP, MALE BEHAVIOR. This phase was often lengthy (detailed below). Several acts and act systems characterized male behavior.

Align Head: The male attempted to keep his head and snout in parallel alignment with the female. If she flexed her neck laterally he did likewise.

Arch Neck and Nudge: The male flexed his neck so that his snout was directed at the top of her head. Occasionally, he tongue-flicked or nudged the top of her head.

Base of Tail Lift: The male used either hindleg to lift the base of the female's tail (Fig. 1). If her hindleg was lying against the base of her tail it was lifted along with her tail. When the female appeared non-receptive, the male often switched frequently from the left side to the right side of the female, using first one hindleg and then the other. Because courtship was often prolonged, the male's claws produced abrasions and bleeding on the female's tail. *Base of Tail Lift* was one of the most common act systems during courtship.

Embrace: The male embraced and held the female with his forelegs just caudal to her forelegs. At other times rather than embracing her he supported himself with his forelegs as he straddled her.

Head or Neck Scratch: The male often scratched the head or neck of the female with one of his forelegs. This act system occurred in intense courtship or during the early stages of courtship.

Head Sway-Tactile Contact: During courtship the male made lateral swaying movements with his head (Fig. 1). Typically his chin or gular region made tactile contact just above the female's eyes. The deviation during swaying was about 10° to 15° from the longitudinal axis. This was a common act system during courtship. In all sequences there was variation in the speed of *Head Sway-Tactile Contact.* Head swaying was slower when the female remained quiescent than when she appeared non-receptive.

Rub Side of Face and Snout: The male gently rubbed the side of the female's face and snout with his snout.

Tactile Tail Contact: The tails of the two animals made tactile contact at three places: base of tail, approximately half the length of the tail, and near the tip. Often there was some intertwining of the tips, and they were intermittently in motion.

PHASE II. COURTSHIP, FEMALE BEHAVIOR. The female's behavior was characterized by fewer act systems.

Lateral Head Jerk: The female rapidly flexed her neck, jerking the head to left or right. Sometimes the angle of deviation from the longitudinal axis equaled or exceeded 90°. This act system was observed several times.

Move Ahead: The female, straddled by the male, moved forward, attempted to move forward, or, in some instances, moved out from under the male.

Move Back: The female backed out from under the male.

Passive Behavior: During all phases most of the behavior of the female was passive, i.e., she lay motionless.

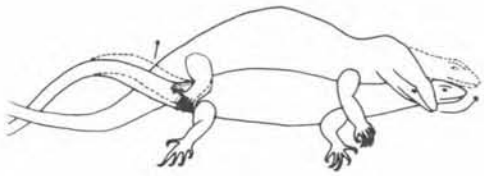

Figure 1. *Base of Tail Lift* and *Head Sway-Tactile Contact* in courtship of *V. timorensis.* Drawn from videotape frame.

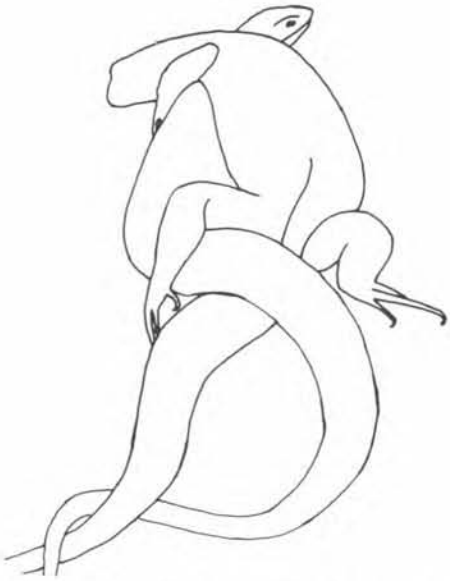

Figure 2. *Draping* during copulation in *V. timorensis.* Drawn directly from 35 mm transparency.

PHASE III. COPULATION. Like courtship this phase was often prolonged (detailed below).

Cloacal Twist: The male twisted his cloacal region below the female's to achieve intromission.

Draping: Sometimes, after achieving intromission the male was draped over the female (Fig. 2). He frequently appeared to be asleep and maintained this position for prolonged periods.

Rhythmic Pelvic Movements: These were movements of the male's pelvic region once intromission was achieved or after a long period of *Draping.* If initiated immediately, with the male alert, his head would be in parallel alignment with the female's head. If started during *Draping,* the male typically maintained the draped position.

Passive Behavior was characteristic of the female during copulation. Occasionally, she became restless, and then the male might resume *Lateral Head Sway-Tactile Contact.* On one occasion, the heads and necks of the two lizards were flexed at a 45° angle to the left as *Rhythmic Pelvic Movements* started. The female then flexed her head, neck, and anterior trunk about 60° to the right. The male then flexed his head, neck, and anterior trunk so that they were realigned.

TEMPORAL SEQUENCE OF BEHAVIORS ACCOMPANYING COPULATION. The following sequence was typical of the intensity and duration of other sequences.

00:00:00: The male was draped over the female *in copulo* at the beginning of the sequence. Intromission had been achieved from the left side.

00:10:16: The male began *Rhythmic Pelvic Movements* while still draped over the female. These pelvic movements occurred approximately once every 7 s.

00:12:40: Intromission was terminated.

00:12:51: The male, still straddling the female, was performing *Base of Tail Lift* and *Head Sway-Tactile* contact.

00:13:56: The male achieved intromission from the right side. They remained *in copulo* for approximately the next 17 min. *Rhythmic Pelvic Movements* occurred throughout, approximately once every 5 s.

00:30:48: Intromission was terminated.

00:30:52: Immediately, without dismounting, the male resumed courtship activity. An intense period of courtship followed with the male frequently adjusting his position and performing numerous courtship activities. While attempting to achieve intromission, the male switched from her right side to her left side 13 times in the next 10 min. *Base of Tail Lift* occurred intermittently and he frequently scratched her head and neck. *Head Sway-Tactile Contact* with gular or snout contact frequently occurred, as did *Rub Side of Face and Snout.* She frequently adjusted her position, and often performed *Lateral Head Jerk.* Sometimes the male restrained her with *Embrace.*

00:41:58: The female backed out from underneath the male.

00:44:40: The male located the female at the other end of the enclosure, mounted her, and resumed courtship activities.

00:47:40: Intromission was achieved from the right side.

00:48:30: Intromission was terminated and intense courtship resumed.

00:52:13: Intromission was achieved from the right side.

00:54:54: Intromission was terminated and was followed again by intense courtship.

00:57:10: Intromission was achieved from her right side. Intromission was followed by 10 *Rhythmic Pelvic Movements.*

00:58:10: Rhythmic Pelvic Movements ceased.

01:00:20: The male was draped over the female and appeared to be asleep. The female occasionally closed her eyes for brief periods but apparently remained awake.

01:35:02 The male was still draped over the female and still appeared to be asleep. A *Rhythmic Pelvic Movement* occurred. This was followed by a *Rhythmic Pelvic Movement* 22 s later and again after 11 more s. Thereafter they occurred every 5 s. The male remained draped over the female.

01:44:02: The male was awake. Intromission was terminated. The male immediately resumed courtship. Videotaping ceased.

DISCUSSION

The observations of Auffenberg (1978, 1981b) on *V. komodoensis* courtship were made in the field, near carrion, and often while monitors were aggregated for feeding. There are similarities between the behavior of my captive *V. timorensis* and wild *V. komodoensis.* There are also differences. In both species tactile and olfactory cues apparently play a prominent role. There is much tongue flicking and licking in both species, especially by the male. However, Auffenberg (1981b) observed some licking and flicking

by females also, but this was of less frequent occurrence than in males. The female *V. timorensis* was not observed to tongue flick or lick the male during the observed sequences.

Scratching of the female by the male is a common tactile cue in both species. In *V. komodoensis* most scratching is apparently on the back of the female while the male is beside her (Auffenberg, 1978, 1981b). In *V. timorensis* the male spent prolonged periods of time mounted on the female. Therefore, most scratching was aimed at the head and neck. In *V. komodoensis* scratching is believed to quiet the female (Auffenberg, 1978, 1981b). The same function appears to be true for *V. timorensis* as scratching was more frequent when the female was restless.

Nudging and rubbing of the female by the male is a common tactile/olfactory cue in both species. This is accomplished with the male's snout. *V. komodoensis* males nudge the side at the insertion of the hindlimb, sides of body, back, and sides of the face (Auffenberg 1978, 1981b). Since my male *V. timorensis* was most often mounted during courtship sequences, nudging and rubbing were mostly confined to the sides of the face and top of the head. Auffenberg (1981b) has suggested that pustules on the face of female *V. komodoensis* may be associated with tactile or olfactory cues. Murphy and Mitchell (1974) observed nudging in a brief courtship encounter of *V. gilleni*.

Infrequent biting of the female by the male was observed in *V. komodoensis* (Auffenberg, 1981b) and *V. bengalensis* (Auffenberg, 1981a). The male *V. timorensis* never bit the female on the body nor did he ever use a neck bite or shoulder bite hold to restrain her. Murphy and Mitchell (1974) did observe shoulder bite holding in *V. gilleni*. In both *V. komodoensis* and *V. timorensis* males may use their front legs to clasp females just behind their front legs. This restrains the female as would neck or shoulder bite holding.

A very common behavior in *V. timorensis* was *Base of Tail Lift*. This behavior occurred more or less continuously while the male was mounted and until intromission was achieved. This also is apparently a tactile cue. However, it could not be determined whether this was a cue that eventually stimulated the female to raise the base of her tail, or whether the male eventually lifted the base of her tail to the correct position for bringing the cloacal openings together. *Base of Tail Lift* was not observed in *V. komodoensis* (Auffenberg, 1981b), but is has been observed in *V. bengalensis* (Auffenberg, 1981a). Auffenberg (1981b) did observe a female *V. komodoensis* raise the base of her tail after a male repeatedly touched the area with his hind foot. This suggests that in *V. timorensis* it may be a cue that eventually causes the female to raise the base of her tail.

A common act in *V. timorensis* is *Head Sway-Tactile Contact*. This behavior was also observed in *V. gilleni* (lateral zig-zag motion of head) (Murphy and Mitchell, 1974), and in *V. bengalensis* (Auffenberg, 1981a). This is another act system which apparently maintains the quiescent state of the female. Its importance in *V. timorensis* seems to be related to male-female head alignment.

The reproductive season is long in *V. komodoensis* (approximately three months for successful coition) and extended pair-bonding of males and females may occur (Auffenberg, 1978, 1981b). In captive *V. timorensis* the reproductive season is short. Some aspects of *V. timorensis* courtship, e.g., duration and intensity, suggest the possibility of short-term pair-bonding, at least during the reproductive season.

ACKNOWLEDGMENTS

I thank Charles Carpenter for numerous courtesies, space, facilities, and for reading the manuscript. Ralph Axtell provided assistance and critically reviewed the manuscript. Financial support was provided by Illinois College. I am grateful to Dr. Loren Hill and the University of Oklahoma Biological Station for facilities and financial support.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 33719.

ANURA

HYLA CRUCIFER CRUCIFER (Northern Spring Peeper). **REPRODUCTION.** Collins (1982. Amphibians and Reptiles in Kansas, 2nd edition: 75-76.) discusses breeding behavior of *Hyla c. crucifer* in Kansas but does not include information of the number of eggs laid by females. Below I present the first available information on the number of eggs laid by a female Kansas *H. c. crucifer*.

On 12 March 1983, Kelly J. Irwin and I collected three male and one female *H. c. crucifer* in a flooded roadside ditch in Cherokee County, Kansas (Sec. 11, T33S, R25N). The males were taken as they called from positions on grass clumps or reeds near the water line. The female was taken by KJI at the time that she emerged from a clump of submerged grass.

The four frogs were maintained together in a gallon glass jar containing ca. 20 mm of water. On 16 March 1983, eggs were observed in the jar, and all frogs and eggs were subsequently preserved. The female had a SVL of 30 mm. A count of the eggs revealed that 702 had been laid.

All specimens were deposited at the Museum of Natural History, University of Kansas. (♂♂ = KU 192722-24, ♀ = KU 192725, eggs = KU 192726.)

This field work was supported by a grant from the Nongame Wildlife Fund of the Kansas Fish and Game Commission (Contract #76). I would like to thank Kelly J. Irwin for

assistance in the field, and Joseph T. Collins for his suggestions and encouragement.

CAUDATA

ANEIDES FLAVIPUNCTATUS FLAVIPUNCTATUS (Speckled Black Salamander). **BEHAVIOR.** Salamanders employ a variety of defensive mechanisms, such as immobility, secretion of noxious substances, cryptic coloration, and antipredator poses (see Brodie, 1977. Copiea 1977:523-535).

During a mark-recapture study of salamanders near Willow Creek, Humboldt Co., California, it was observed that the majority of adult *A. flavipunctatus* fled vigorously upon exposure, while juveniles remained immobile. The same behavior has been documented for *A. aeneus* (Brodie, 1974. Herpetologica 30:79-85).

On one occasion (4 March 1983) however, a 26 mm *A. flavipunctatus* exhibited a defensive posture during toe clipping. The animal stood high on its outstretched legs and arched its back. It gently rocked back and forth, much like the sympatric *Ensatina eschscholtzi* (Stebbins, 1954. Univ. Calif. Publ. Zool. 54:47-124). The distal third of its tail undulated laterally in a slow rhythmic motion. The display continued for over one min, and was not discontinued until well after it was set back into the depression of its rocky cover.

This was the only such display witnessed for the species during 93 observations in the study plot and dozens of field observations elsewhere. It is believed that this display has not been previously reported for the species.

SAURIA

CALLOPISTES MACULATUS (Chilean macroteiid). **DIET.** *Callopistes maculatus* is a large ground-dweller teiid of the central Chile scrublands (Donoso-Barros, 1966, Reptiles de Chile; Fuentes, 1976, Ecology 57:3-17). The food habits of *C. maculatus* are highly variable; while Donoso-Barros (ibid.) points out that "insects and small reptiles" comprise its diet, Fuentes (ibid.) shows that *C. maculatus* consumes vegetation — fruits — to a great extent (relative frequency of vegetation in the diet = 0.69 vs 0.30 of arthropods). To our knowledge, no studies have reported that *C. maculatus* includes carrion in its diet; this note documents small mammal carrion consumption by *C. maculatus*.

The observations were made during a period of small mammal snap-trapping, in December 1981; the study site was a scrubland patch in Los Dominicos (20 km E of Santiago;≈ 1,000 masl). On 3 occasions individual *C. maculatus* were found feeding on the body of a snap-trapped rodent; at each time, the lizards were observed from a distance without disturbing them. The lizards stopped feeding between 5 to 10 min after they were discovered; in all 3 cases, *C. maculatus* were eating the mid-body of the rodents, which were *Akodon olivaceus* (two times) and *Octodon degus*. We have no observations of *C. maculatus* preying on small mammals, such as *Gambelia wislizeri* apparently does upon *Perognathus longimembris* (Pietruszka, Wiens and Petruszka, 1981, J. Herpetol. 15:248-250).

Callopistes maculatus exhibits high metabolic demands, as expressed by its activity temperature of 40° C (Fuentes and Jaksić, 1979, Copeia 1979:546-548). Fruits are a supplementary food item when arthropod availability is insufficient to fulfill the energetic requirements (Fuentes, ibid); the consumption of carrion could be another such alternative. These observations suggest that *C. maniculatus* feeds opportunistically, taking advantage of the potential food items available.

Field work was supported by grant DIUC 75/81.

SERPENTES

AGKISTRODON CONTORTRIX LATICINCTUS (Broad-banded Copperhead). **COMBAT.** In this note I report an observation of an apparent combat dance between two free-living broad-banded copperheads *(Agkistrodon contortrix laticinctus).* On 20 June 1979, I was camped on a vegetated sand and gravel bar on the Brazo River, just upstream from the State Highway 4 bridge crossing about 11 km north of Palo Pinto, Texas. At ca. 0930. The barking of my pet dog drew my attention to a small opening in the vegetation of the sandbar. In the opening were two large *A. c. laticinctus* performing a combat dance in which they were apparently so engrossed that neither my presence nor my dog's (which I had calmed) interrupted the behaviors. The two snakes had the posterior portion of their bodies in contact while the anterior one-third of their bodies were raised and swaying back and forth. Occasionally, one or the other lowered its body to the ground (Fig. 1), but during the swaying activity, both returned to a vertical position. After a short period of swaying and an occasional jerking motion, the heads appeared to make contact and the bodies became encoiled (Fig. 2). The "top" snake then pressed on the dorsal side of the opponent's head in an apparent effort to force the other snake toward the ground (topping). After ca. five min of repeating the above-mentioned behavior, the pair separated and crawled away in generally opposite directions.

Figure 1. *Agkistrodon contortrix laticinctus* in combat. One combatant has lowered itself to the ground.

Figure 2. Topping during combat of *Agkistrodon contortrix laticinctus.*

To my knowledge, there are no published accounts of combat behavior of *A. c. laticinctus* in the wild. The purpose of combat behavior in snakes is not well understood though suggested functions include territorial defense, definition of social dominance, competition for females, and competition for food items.

I would like to thank Dr. Charles C. Carpenter and Mr. Stanley Wilson for reviewing this note.

BOTHROPS SCHLEGELII (Eyelash viper). **COLORATION.** Among neotropical pit vipers, the eyelash viper, *Bothrops schlegelii* (Berthold) represents an example of extreme variation with respect to color and pattern. The considerable polychromatism of these characteristics is unrivaled in other members of the pit viper assemblage. Several descriptions of overall pattern have been reported, although individuals may possess unique combinations of color and pattern. Known variants apparently do not conform to natural patterns of geographic distribution and can be ascribed to single clutches (Antonio, 1980. Herpetologica 36(3):231-233).

This report describes an unusual variant in which the common pattern of dorsal blotching is replaced and expressed as longitudinal striping. The individual in question, is a small

male (Fig. 1), CRE 3619 (Costa Rica Expeditions, Department of Biology, University of Miami), snout to vent length 360 mm, tail length 78 mm, from Venado de Guatuso, Alajuela Province, Costa Rica, elevation 252 m. The ventral scales number 159, the caudals 58, and the dorsal scale row formula is 21-19-17. These and other scale characteristics of this specimen lie within the known variation of other Costa Rican *B. schelgelii.*

The dorsal ground color on the head and body is pale grey infused with minute black punctations. These punctations may form aggregations appearing as larger flecks, evenly distributed over the dorsum and resulting in a fine reticulate pattern. Laterally the larger flecks are linked longitudinally to form small, faint, elongate strands, dashes or narrow lines. The dorsal markings of the head consist of three pairs of brown "dumb-bell" shaped blotches outlined sharply by a thin margin of black. The anterior pair, on frontorostral region, are fused posteriorly forming a bloated "V". The second pair are elongate (length about 3X width), begin just medial to the supraocular scales and diverge posteriorly, ending just anterior to the level of the oral rictus; when viewed from above, they appear parallel to the laterally adjacent postocular stripes. The postocular stripes are similar in coloration, being brown medially and outlined clearly by black. The third and posterior pair of these blotches begins medial to the terminal portions of the second pair, and also diverge posteriorly. They extend down the dorsum of the neck as two thin brown lines, contiguous with the paired, brown dorsal body stripes. These latter stripes are one and one-half to two dorsal scale rows wide and are also outlined by black. They are broken into a series of elongate blotches posterior to the level of the 10th ventral. They resume their unbroken appearance near the 17th ventral for the right stripe and the 28th for the left. Anteriorly, and at mid-body, each stripe occupies a single (longitudinal) scale row, lateral to the three most dorso-medial rows, which are distinctly grey. The six scale rows ventro-lateral to the brown stripes are also grey in color. The outermost dorsal scale rows, adjacent the ventrals, are either immaculate pale yellow or dark brown. Near mid-body, where the scale rows reduce from 21 to 19, the grey coloration of the flanks occupies five scale rows on each side rather than six as observed anteriorly. The brown dorso-lateral stripes and the medial grey region, at this level remain unchanged. However, posteriorly, at the level of reduction from 19 to 17 scale rows at approximately ventral 103, the dorsal grey and lateral brown stripes occupy slightly altered positions. At this level, the dorsal grey area covers the central scale row (most dorsal) and the medial 1/2 of the immediately adjacent row, on each side. The brown stripe includes the distal 1/2 of these latter two rows and 1/2 of the next lateral row; the remainder of which is grey, as are the four lateral contiguous rows, on each side. The two outermost rows on each side, adjacent to the ventrals, at this level are similar to those anteriorly.

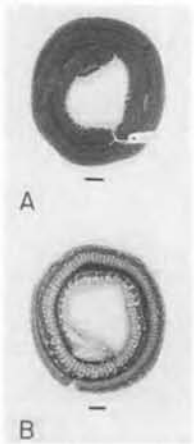

Figure 1. Dorsal (A) and ventral (B) views of *Bothrops schlegelii,* CRE 3916, indicating pattern of longitudinal stripes. Bar equals 10 mm.

In addition to those dorsally, there are also stripes along the lower aspects of each flank, at the junction of the ventrals and the dorsal scale rows. The coloration of these two linear stripes is dark brown, outlined above and below by a thin margin of pale yellow. In other specimens of *B. schlegelii* there are typically alternating patches of yellow and brown in a similar position along the lower flanks. With respect to the specimen on this report, the dark or brown patches appear to be fused in series, along the posterior 2/3 of the body, giving rise to a longitudinal stripe. The dorsal yellow outline of this stripe is restricted to the second dorsal scale row above the ventrals, while the row directly adjacent to the ventrals is characteristically brown. Likewise, the outermost 1/4 of each ventral is also pigmented brown. The medial (ventral) yellow margin of the stripes exists as a series of light spots, one per ventral, which viewed from a distance form an unbroken line. The very central portions of the ventrals about 1/4 to 1/3 their total widths, are pale yellow with an infusion of light brown punctations. These punctations gradually increase in density posteriorly. The anterior ventrals are nearly immaculate pale yellow, while the ventral portion of the tail is nearly tan in color.

While the fusion of dorsal blotches and the expression of longitudinal stripes has been reported for a variety of snake taxa, in pit vipers previous observations involve only rattlesnakes (*Crotalus* spp.) and the copperhead *(Agkistrodon contortrix)* of temperate North America (Gloyd, 1958. Bull. Chicago Acad. Sci. 10(12):185-195). This situation is presumed rare for *B. schlegelii* as this represents a single case, of 71 individuals examined from Costa Rica. It is also noteworthy in that the pattern of longitudinal striping is nearly complete along the entire length of the body, except for a short region anteriorly. This is rare in *Crotalus* as most reported aberrants exhibit fusion of only a few dorsal blotches (Schuett and Kraus, 1982. Herp. Rev. 13(1):17-18) restricting the striped pattern to a small portion of the body length.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **COLORATION.** In October, 1979, nine *Crotalus viridis viridis* were collected 1 km south and 1 km east of Abarr, Yuma County, Colorado by Mr. Carl Allphin, now of Haxtun, Colorado. One of these specimens, a female, is entirely patternless except for a single black band at the base of the rattle (Fig. 1). The olive-gray ground color is typical of specimens from this population. Pattern melanin across the animal's dorsum is restricted to small dots which are discernible only upon reasonably close inspection (Fig. 2). H. K. Gloyd (1958, Bull. Chicago Acad. Sci. 10:185-195) described a similar pattern anomaly in a *C. atrox.*

In addition to the conspicuous absence of pattern melanin, the female *viridis* also lacks all of the usual cream-colored blotch borders and facial stripes. Despite the aberrancies of coloration, this specimen does not differ from the eight normal specimens in terms of scutellation or body proportions. The snake died in an *Arizona hinshawi (Salmonella arizona)* epidemic in January, 1980, before any attempts at breeding could be undertaken. It is now deposited in the U.S. Fish and Wildlife Service collection in Fort Collins, Colorado (USFWS 02435).

Eleven similar non-albinistic, patternless crotalids have been reported in the recent literature (Gloyd, 1958; Fitch, H. S., 1959, Herpetologica 15:21-24; Nickerson, M. A. and Mays, C. E., 1968, Wasmann J. Biol. 26:125-131; Irwin, K. J., 1979, Herp. Rev. 10:85; Holmback, E., 1981, Herp. Rev. 12:70; Quinn, H., 1981, Herp. Rev. 12:79-80). These include

Figure 1. Patternless *Crotalus v. viridis.*

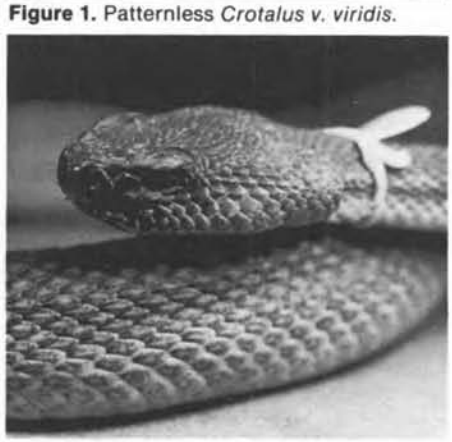

Figure 2. Close-up of patternless *Crotalus v. viridis.* Note small dots of melanin on scales.

five *Agkistrodon contortrix*, three *Crotalus viridis*, one *C. atrox*, one *C. scutulatus*, and one *C. lepidus*. Nickerson and Mays (1968) did not report the sex of the *C. viridis* they described; however, of the remaining ten specimens, nine are males.

The discovery of five patternless male copperheads in one population led Fitch (1959) to suggest that the trait might be a sex-linked recessive. That conclusion is not necessarily invalidated by the female described above, or by the nearly patternless female *C. scutulatus* described by Nickerson and Mays (1968). Pattern inheritance is sufficiently complex that superficially similar abnormalities may stem from mutations at a variety of loci. Additionally, so little is presently known about the genetics of color patterns that the possibility of different genetic mechanisms in different genera must also be considered.

ELAPHE OBSOLETA (Black Rat Snake). **AUTOPHAGY.** In August 1982 a juvenile *Elaphe obsoleta* (345 mm total length) from Carbondale, Jackson Co., Illinois, was fed a 5-day old mouse. While swallowing the mouse, the snake took a loop of its own tail in its mouth. Attempts to induce the snake to release itself were unsuccessful. During the next 45 min, the snake ingested the mouse and ca. 10 cm of itself. The snake then yawned and withdrew its body, leaving the mouse in its stomach. The snake suffered no ill effects from this incident. However, on 10 November 1982 this snake was found dead in a "figure-eight" position, having swallowed itself again (Fig. 1). Why the snake committed autophagy the second time is unknown, but it and its litter mates had been hatched from eggs incubated at a low temperature (ca. 20-21° C) and often showed abnormal behaviors (e. g., lying on their backs).

Autophagy by snakes seems rare. Mitchell, Pague, and Early (1982, Herp. Review 13:47) described another incident of autophagy by an *E. obsoleta*. Their case differed from the one described above in that it apparently was induced by a sudden temperature change. I agree with these authors that early observations of autophagy may have contributed to the hoop snake myth. In the first incident described herein, the snake continuously moved in a roughly circular path. Similar movements by snakes swallowing themselves may have been the basis for the "rolling" of snakes in the myth.

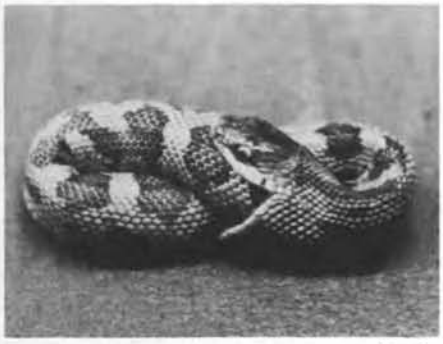

Figure 1. Results of autophagy committed a second time by a juvenile *Elaphe obsoleta*.

The first incident reported here shows that autophaging snakes can free themselves without losing ingested food.

The specimen is deposited in the herpetology collection of the Department of Zoology of Southern Illinois University at Carbondale (SIUC R-1796). I thank Gail Johnston for Fig. 1.

LAMPROPELTIS TRIANGULUM ANNULATA (Mexican Milk Snake). **SIZE.** The largest known specimen of *L. t. annulata* was 99.1 cm (Conant, 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton-Mifflin). Our specimen, a male, was collected D.O.R., 25 August 1983, approximately 2115 hrs, shortly after a thunderstorm. The locality was near Hebbronville, 14.4 km S of the junction of highways 285 and 1017, on 1017, Jim Hogg County, Texas. It measured 104.4 cm (89.7 cm SVL, 14.7 cm TL), thus being the largest known specimen by 5.3 cm. It had been recently run over as there was still caudal reflex action evident. Despite being D.O.R., there is no obvious external or internal structural damage that could have increased the total length. The specimen was laid out flat, but not stretched, and measured prior to preservation. Aside from the large size, the specimen was typical for *L. t. annulata* in other features of color, pattern and scutellation (Williams, 1978. The Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*. Milwaukee Public Museum). The specimen was deposited in the Texas Cooperative Wildlife Collection (TCWC 61627), Texas A&M University.

STORERIA DEKAYI DEKAYI (Northern Brown Snake). **COLORATION.** Hensley (1959, Pub. Mus. Mich. State Univ. 1(4):154) noted an albinistic specimen of *S. d. dekayi* from Pennsylvania. Smith (1961, The Amphibians and Reptiles of Illinois, Ill. Nat. Hist. Surv. Bull. 28) and Thrall (1971, Trans. Ill. Acad. Sci. 64(4):400) each reported single albino specimens of *S. d. wrightorum* from Illinois. Marion and Chandler (1983, Herp. Rev. 14(2):47) reported an albinistic individual of the latter subspecies from Alabama.

On 12 May 1975 the Baltimore Zoo received an albinistic *S. d. dekayi* that was collected at a vacant lot at Wicomico and Monroe Sts., Baltimore, Maryland. This specimen, a female ca. 20 cm total length, had a ground color of buffy-white with a double row of very light brown spots down the length of the back. Temporal bars and stippling on top of the head were of the same light brown color. The iris of the eye was bronzy and the pupil appeared dark red in strong light.

On 24 July 1975 this snake gave birth to seven live and two dead young. Two of the living young were colored exactly as the mother; all of the others were normal colored. The two albinistic young died after about two months and were not preserved. The mother died after 11 months in captivity and a notation on her record card indicates that she was preserved. However, I am unable to locate this specimen. It is believed that she may have been among a group of about 30 small preserved snakes that were stolen from the Baltimore Zoo's museum collection in 1978.

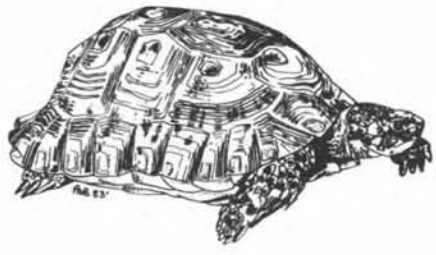
TESTUDINES

PSEUDEMYS RUBRIVENTRIS (Red-bellied Turtle). **PREDATION.** Bullfrogs *(Rana catesbeiana)* consume a diverse array of animal foods, including turtle hatchlings (Corse and Metter, 1980. J. Herp. 14:231-238). Reference to bullfrog predation on the young of snapping, stinkpot, painted and ornate box turtles was made by Ernst and Barbour (1972. Turtles of the United States). Recently, Metter (pers. comm.) indicated that the two turtles reported in his 1980 frog dietary paper were both newly hatched; one was a *Graptemys geographica*, the other a *Pseudemys scripta*. A 57 mm long specimen of *Terrapene carolina triunguis* was documented from the gut of an Oklahoma bullfrog (McCoy, 1967. Proc. Okla. Acad. of Sci. 46:44-45). Sherman Minton has seen bullfrogs eat *Graptemys* hatchlings in Indiana (pers. comm.) and Madeleine Linck watched a bullfrog taking newly released hatchling snapping turtles *(Chelydra serpentina)* at Great Meadows National Wildlife Refuge, Concord, Massachusetts (pers. comm.).

On 10 July 1983 at Crooked Pond, Plymouth, Plymouth Co., Massachusetts a pair of red-bellied turtle hatchlings *(Pseudemys rubriventris)* were discovered missing after confinement in a vinyl coated 1 x ½-inch wire mesh holding pen. This pen measured 120 x 120 cm and was staked at a water depth of 45 cm approximately 3 m from shore. Although this pen was covered with the same mesh to discourage birds and other predators from harming the occupants, a bullfrog had somehow gained access. I captured and palpated the frog and became suspicious when I felt a hard lump in his abdomen. The frog was sacrificed and dissected immediately, whereupon the two missing turtle hatchlings were discovered dead in its stomach. The frog, an adult male, was 120.2 mm in SVL while the hatchlings were 33.2 mm and 32.4 mm in CL. This represents the first report of frog predation on red-bellied turtles. All specimens de-



scribed herein are deposited in the Worcester State College collection (TEG 07831 - 07833).

TERRAPENE CAROLINA CAROLINA (Eastern Box Turtle). **SCUTATION/DEATH.** In early June 1983 an entire, mud encrusted Eastern box turtle shell was collected from the Bellefonte Nuclear Plant site in Jackson County, Alabama. The shell was originally collected for the purpose of obtaining a complete box turtle skeleton. The plastron was shut with the left front foot protruding from the side, and the bones were held together by patches of dried skin that remained attached. Upon cleaning the shell, an aberrant vertebral scute pattern was exposed. The first and fifth vertebral scutes were formed and positioned normally, but the three middle scutes were replaced with six malformed scutes arranged in an asymmetrical pattern. A slight dorsal ridge was broken into small sections on each vertebral scute. The right side of the shell contained the normal number of four costal scutes, while the left side had five due to the additional vertebral scute.

Of special interest concerning the removal of the skeleton was the discovery of a small (7 mm) pit viper fang embedded through a dried skin patch in the left shoulder area. The fang was unbroken and was apparently shed as the bite was inflicted. The high copperhead density in this region and the small fang length and diameter serve to indicate the bite was most likely delivered by a young Northern copperhead *(Agkistrodon contortrix mokeson),* probably a yearling. This evidence appears to indicate the turtle's death resulted from a venomous snake bite, with the left foot protruding from the shell due to the swelling that occurred prior to death. Whether the bite resulted from the box turtle inadvertently crawling over the snake or attempting to feed on it is purely conjectural.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

ANURA

ACRIS CREPITANS BLANCHARDI (Blanchard's Cricket Frog). USA: TEXAS: Stephens Co: 0.6 km N Crystal Falls on FM 578 in Clear Fork of Brazos River. 23 October 1983. C. T. McAllister. Verified by R. Ward. North Texas State University Herpetological Collection (NTSUHC A75-80). First record for county and nearly fills distributional hiatus in Brazos River watershed (Raun and Gehlbach. 1972. Amphibians and Reptiles in Texas. Dallas Mus. Nat. Hist. Bull. 2). This species was recently reported from adjacent Young County (McAllister and Wooten. 1982. SSAR Herp. Review 13:24) and should inhabit additional northwestern branches of the Brazos River.

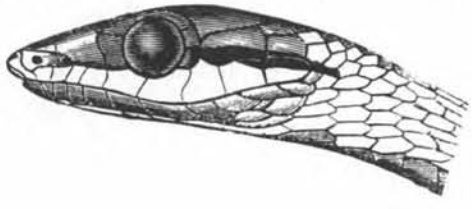
CAUDATA



AMBYSTOMA MABEEI (Mabee's Salamander). USA: VIRGINIA: York Co: 4.3 km S Yorktown, on north side of James River, Harwood's Mill Reservoir watershed property. 27 May 1983. R. Hodge, B. Ensley, R. Cross and D. West. Verified by R. Hodge and C. Pague. Peninsula Nature and Science Center (PNSC 83-12). Third Virginia record, first record north of James River. Extends range ca. 60 km north (Mitchell and Hedges. 1980. Brimleyana 3:119-121). Six additional specimens found and released at the same locality from 25 May to 7 June.

Submitted by **BARRY ENSLEY,** 95 Kitty Drive, Grafton, Virginia 23692 and **ROBERT CROSS,** 12721-17 Nettles Drive, Newport News, Virginia 23606, U.S.A. ●

SAURIA

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: ALABAMA: Mobile Co: Mobile, Church Street Cemetery. 25 November 1983. Harold A. Dundee. Verified H. A. Dundee. Tulane University (TU 19750). First coastal record for the state. Approximately 278 airline km SW nearest Alabama record in Eufaula (Mount, R. H. 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Press) and 198 airline km ENE of New Orleans, Louisiana where it has been established over 40 years. I have been collecting at this cemetery and elsewhere in Mobile for over 20 years, and this is my first encounter with the Mediterranean gecko there. This occurrence may be due to natural spread from nearby port facilities, or by introduction on construction materials or plants.

TRETIOSCINCUS BIFASCIATUS COLOMBIA: Isla Providencia (=Old Providence Island, in the western Caribbean about 150 km east of Nicaragua). Near Santa Isabel. 22 April 1969 (LACM 135548); Near Rocky Point 30 April 1969 (LACM 135549). Collected by N. J. Scott in rock cobble under mango trees. Verified by S. C. Ayala. Deposited in Los Angeles County Museum of Natural History. Peters and Donoso-Barros (U.S. Natl. Mus. Bull. 297(II):262) cited the range of *T. bifasciatus* as "northern South America, Dutch Leeward Islands and Magarita Island, Venezuela". The dorsal scales of the Providencia specimens are very weakly keeled, like those of *T. agilis* (Ruthven), but unlike *T. agilis* the large prefrontal scales are in broad contact. *Tretioscincus bifasciatus* is common in northern Colombia, and may have reached the island by rafting on floating vegetation from the Atrato or Magdalena rivers during winter floods, or in cargo transported by boat. It is not known whether *Tretioscincus* has established itself on Isla Providencia.

Submitted by **NORMAN J. SCOTT, JR.,** U.S. Fish and Wildlife Service, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, and **STEPHEN C. AYALA,** 307 12th Street, Petaluma, California 94952, U.S.A. ●

SERPENTES

LAMPROPELTIS CALLIGASTER RHOMBOMACULATA (Mole Kingsnake). USA: VIRGINIA: Roanoke Co: Blue Ridge Parkway mile post 117.3, approximately 1 km SE Roanoke city limits. Elevation 340 m. 17 July 1980. W. H. Martin. Verified by Joseph C. Mitchell. U.S. National Museum (field number 110175). Known Virginia range lies entirely east of the Blue Ridge. This record is 3 km west of the Blue Ridge but the Blue Ridge is penetrated here by the Roanoke River valley.

Submitted by **W. H. MARTIN,** Rt. 3, Box 804, Harpers Ferry, West Virginia 25425, U.S.A. ●

NERODIA RHOMBIFERA RHOMBIFERA (Diamondback Water Snake). USA: TEXAS: Grimes Co: 1.6 km N Navasota (probably Navasota River or tributaries). 26 April 1948. J. M. Schmidt, K. P. Schmidt and R. F. Inger. Verified by A. Resetar. Field Museum of Natural History (FMNH 55007). New county record, fills distributional hiatus in the Trinity-Brazos area (Raun and Gehlbach. 1972. Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. 2).

Submitted by **CHRIS T. McALLISTER,** Renal-Metabolic Lab (151-G), Veterans Administration Medical Center, Dallas, Texas, 75216, U.S.A. ●

PITUOPHIS MELANOLEUCUS (Pine Snake). USA: ALABAMA: Crenshaw Co: 15.8 km N of Luverne, Junction of US 331 and Crenshaw Co 3.R18E; T10N; S7; NE¼; SW¼. 8 May 1983. P. N. Lahanas and J. C. Godwin. Verified by P. N. Lahanas and J. C. Godwin. Auburn University (AUM 32239). New county record, collected midway between the range of *P. m. melanoleucus* to the north and *P. m. mugitus* to the south (Mount, R. H. 1975. The Reptiles and Amphibians of Alabama. Alabama Agric. Exper. Sta., Auburn, AL) and may be intergradient.

RHADINAEA FLAVILATA (Pine Woods Snake). USA: FLORIDA: Palm Beach Co: Boynton Beach, NE Jct. Old Boynton Rd. and Lawrence Rd. one adult male specimen, 27 March 1983; one unsexed specimen, 1 April 1983. Jeffrey A. Gottlieb. Verified by Richard C. Bothner. St. Bonaventure University collection (# 1732, 1704). First records for county and extend range 70 km southeast (Ashton and Ashton, 1981. Handbook of Reptiles and Amphibians of Florida, Part 1: The Snakes. Windward Publishing Inc., Miami, Fl.).

Submitted by **JEFFREY A. GOTTLIEB,** Department of Biology, St. Bonaventure University, St. Bonaventure, New York 14778, U.S.A. ●

TROPIDOCLONION LINEATUM (Lined Snake). USA: NEW MEXICO: Torrance Co: 16 km W Clines Corners. Date unknown. L. Anderson. Verified by W. G. Degenhardt. Museum of Southwestern Biology, University of New Mexico (UNM 6150). 5.6 km S Chilili, T7N, R7E (Chilili Land Grant). 2 June 1983. Paul C. Wiklund. Verified by M. A. Williamson and W. G. Degenhardt. (UNM 39935). 8.2 km N Mountainair, T4N R7E, Sect. 5. 10 September 1983. M. A. Williamson. (UNM 39934). Grassland to open woodland above 2000 m (Wheatgrass, Grama, Junipers, and some Pinyon). These specimens extend the known range 75 km S and 95 km W of previously reported localities (Williamson and Scott. 1982. SSAR Herp. Review 13(1):26) and are the first reported records for Torrance County. The distribution of this species in New Mexico is probably more widespread than supposed, and this snake should be looked for in other parts of New Mexico where moisture conditions allow its survival.

Submitted by **MICHAEL A. WILLIAMSON,** 7401 Central NE, Albuquerque, New Mexico 87108, U.S.A. and **WILLIAM G. DEGENHARDT,** Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87130, U.S.A. ●

MORE CORRECTIONS OF ERRONEOUS AMPHIBIAN AND REPTILE RECORDS FROM COLORADO

BUFO BOREAS (Western Toad). USA: COLORADO: Grand Co: 16 km SW Kremmling. 7 June 1958. T. P. Maslin and D. Davis. Identified by G. Hammerson, verified by H. M. Smith. Univ. Colorado Mus., Boulder, UCM 11010. Erroneously reported as *Bufo woodhousii* by Maslin (1959, Univ. Colorado Stud., Ser. Biol. 6:14). Negates only *B. woodhousii* record for county.

EUMECES MULTIVIRGATUS (Many-lined Skink). USA: COLORADO: Larimer Co: 6.4 km E Wellington. 13 June 1911. J. Henderson and R. M. Butters. Identified by G. Hammerson, verified by H. M. Smith. UCM 224. Erroneously reported as *Eumeces obsoletus* by Ellis and Henderson (1913, Univ. Colorado Stud. 10:80). Reported under museum specimens of *E. multivirgatus* and literature records for *E. obsoletus* by Maslin (op. cit., p. 46), as was a specimen (UCM 225, apparently lost) from Greasewood Lake, SE Osgood, Weld Co., collected by J. Henderson, 23 June 1912 (reported as *E. obsoletus* by Ellis and Henderson, loc. cit.). Maslin's listing of these specimens under the literature records for *E. obsoletus* is an obvious *lapsus*—he undoubtedly examined the specimens and listed them correctly under *multivirgatus.* Further evidence that Ellis and Henderson misidentified *E. multivirgatus* as *E. obsoletus* is provided by their figures 15 and 16, plate III, in which photographs of obvious specimens of *multivirgatus* are labeled *"Eumeces obsoletus."* Smith et al. (1965, Univ. Colorado Stud., Ser. Biol. 15:33, 40) based their records of *E. obsoletus* from Larimer and Weld counties on these erroneous published records. In summary, all reports of *E. obsoletus* from Larimer and Weld counties are based on *E. multivirgatus.*

PHRYNOSOMA CORNATUM (Texas Horned Lizard). USA: COLORADO: Archuleta, Boulder, Denver, and El Paso counties. Maslin (op. cit., p. 37) recorded *P. cornutum* from these counties and indicated that the specimens from Boulder and Denver possibly were escaped pets. Smith et al. (op. cit.) nevertheless mapped *P. cornutum* as occurring in Boulder and Denver counties, but they listed no additional specimens from that area. Texas horned lizards periodically are picked up by travelers and appear in cities along the base of the Front Range, but there is no evidence that any introduced populations are established north of the Arkansas River. The records from Archuleta and El Paso counties originated with Cope (1900, Rep. U.S. Natl. Mus. for 1898, p. 435) who listed specimens with identical museum numbers and collection data under both *P. douglassii* and *P. cornutum.* Most of these specimens are still in existence in the National Museum; they are *P. douglassii* and were correctly reported as such by Yarrow (1882, Bull. U.S. Natl. Mus. 24:68). In summary, populations of *P. cornu-*

tum have not been validly documented in any of the counties listed above.

COLUBER CONSTRICTOR (Racer). USA: COLORADO: Boulder Co: Boulder. 23 May 1905. Collector unknown. UCM 254 (apparently lost). Altona. 14 July 1912. N. deW. Betts. UCM 255. Both specimens were reported as *Masticophis flagellum* by Ellis and Henderson (op. cit., p. 105) and Maslin (op. cit., p. 57). Smith et al. (op. cit.) based their record of *M. flagellum* from Boulder County on these literature records. I have examined UCM 255; it is a juvenile *C. constrictor*. The reported length (295 mm) of UCM 254 is too small for even a hatchling *M. flagellum;* the specimen undoubtedly was another juvenile *C. constrictor*. Further evidence that Ellis and Henderson misidentified *C. constrictor* juveniles as *M. flagellum* is provided by their figures 32 and 33, plate VII, in which photographs of a juvenile *C. constrictor* are labeled *"Zamenis [=Masticophis] flagellum." Coluber constrictor* is abundant in Boulder County, but the nearest occurrence of *M. flagellum* is 140 km to the southeast.

THAMNOPHIS ELEGANS (Western Terrestrial Garter Snake). USA: COLORADO: County unknown: Rio Grande. June 1873. H. W. Henshaw. USNM 8418. Yarrow's (1875, Wheeler Survey, vol. 5) record of *Eutaenia (=Thamnophis) sirtalis dorsalis* from Rio Grande, Colorado, has been the basis for all of the numerous subsequent reports of *T. sirtalis* from the San Luis Valley in south-central Colorado (e.g. see Fitch, 1980, Cat. Am. Amph. Rep. 270.1-270.4). One of the two specimens (now USNM 8418) upon which Yarrow's record was based is still in existence; it is an example of *T. elegans* (Hahn, 1968, M.S. thesis, Louisiana State Univ., Baton Rouge; pers. observ.). Ruthven (1908, Bull. U.S. Natl. Mus. 61:140) evidently examined all specimens of *Thamnophis* in the National Museum (where Yarrow's specimens were deposited) and listed a specimen from Rio Grande,Colorado, as *T. ordinoides elegans (=T. elegans)*. He listed no records of *T. sirtalis* from southern Colorado. In summary, there are no adequately documented records of *T. sirtalis* from the San Luis Valley, Colorado.

NEW HERPETOLOGICAL RECORDS FOR THE MEXICAN STATE OF AGUASCALIENTES

We herein report new records for the state of Aguascalientes. All specimens are in the private collection of Larry David Wilson (LDW) and will be deposited in the University of Kansas Museum of Natural History upon completion of a study on the amphibians and reptiles of the state. All specimens were collected and their identifications verified by us.

TOMODACTYLUS NITIDUS. Arroyo los Puercos, Sierra Fria, ca. 3 km N Congoya, 8 August 1979, LDW 5343. The nearest known locality is in Jalisco and is ca. 200 km SW of the Aguascalientes locality (Dixon, J. R., 1957, Texas J. Sci. 9:379-409 [map]). However, the species was believed to have been heard calling 1.6 km N Santa Rosa, Zacatecas, in the Rio Juchipila canyon (Baker, R. H., R. G. Webb, and P. Dalby, 1967, Amer. Midl. Nat. 77:223-226), a locality somewhat intermediate between the Jalisco and Aguascalientes localities.

DRYMARCHON CORAIS. 4.7 km W El Sauz, 5 August 1979, LDW 5294. The closest locality is in Jalisco and is ca. 200 km SW of the Aguascalientes record (McCranie, J. R., 1981, Cat. Amer. Amph. Rept. 267 [map]).

ELAPHE TRIASPIS. 3.5 km W El Sauz, 7 August 1979, LDW 5329. The nearest locality is Mezquital del Oro, Zacatecas (Boulenger, G. A., 1894, Catalogue of the snakes in the British Museum (Natural History), Vol. II, Taylor and Francis, London), and is some 105-110 km SSW of the Aguascalientes record.

SALVADORA BAIRDII. 4 km S Ciénega, Sierra de Laurel, 13 August 1979, LDW 5405. Fills in the geographic hiatus from states to the northwest and south (Smith, H. M. and R. B. Smith, 1976, Synopsis of the herpetofauna of Mexico, Vol. 3, John Johnson, N. Bennington, Vermont). The species was cited from Aguascalientes in a general list (Velasco, A. L., 1896, Geografia y estadistica del estado de Aguascalientes. Geografia y estadistica de la Republica Mexicana. Vol. 17, Secr. Fomento, México, D. F.), however, no actual specimens were heretofore known from the state.

TANTILLA BOCOURTI. Ciénega, Sierra de Laurel, 2 August 1979, LDW 5263; 4 km S Ciénega, Sierra de Laurel, 6 August 1979, LDW 5316; Mesa la Canoa, nr. El Ocote, 12-13 August 1979, LDW 5384, 5425-27. Fills in a geographic hiatus between specimens from Jalisco (McDiarmid, R. W., J. F. Copp, and D. E. Breedlove, 1976. Nat. Hist. Mus. Los Angeles Co., Contrib. Sci. 275:1-17 [map]) and Zacatecas (McCranie, J. R., 1977, Southwestn. Nat. 22:275).

THAMNOPHIS MELANOGASTER. 3.9 km N Las Negritas, 31 July 1979, LDW 5239-42; Palo Alto, 31 July 1979, LDW 5245; Arroyo los Puercos, Sierra Fria, ca. 3 km N Congoya, 8 August 1979, LDW 5342. Fills in a geographic hiatus as the species is known from surrounding states (Smith, H. M. and R. B. Smith, 1976, op. cit.). The name *Tropidonotus mesomelanus*, a synonym of *Thamnophis melanogaster*, was included in a general list for the state (Velasco, A. L., 1896, op. cit.), however, no specimens were previously known from the state.

FIRST RECORD OF THE COLUBRID SNAKE, *Xenodon rhabdocephalus* (WIED), FOR VENEZUELA

A study of some Venezuelan specimens of the genus *Xenodon* deposited in the collections of the Museo de Biología de la Universidad Central de Venezuela (MBUCV), Estación Biológica de Rancho Grande (EBRG) and Museo de Historia Natural La Salle (MHNLS), revealed that five of them belong to the species *Xenodon rhabdocephalus* (Wied), not previously recorded in Venezuela. The identification of all specimens was determined by Alfredo Paolillo O. Locality and data for the five specimens follows:

MHNLS 7680, 1 ♀, San Martín de Turumbán, rio Cuyuni, Estado Bolívar, M. Lentino coll., 16/VIII/1979; MBUCV 1665, 1 ♂, Cerro Lema, Estado Bolívar, J. Steyermark coll., VIII/1961; EBRG 1574, 1 ♀, Rio Puruname, Atabapo, Territorio Federal Amazonas, P. Piñate coll., 5/VI/1982; EBRG 1136, 1 ♂, Cucurital, Caño Caname, Territorio Federal Amazonas, J. Cerda coll., 1/V/1979; MBUCV 8092, 1 ♂, Minas de Triana, rio Chicanán, Estado Bolívar, E. Rutkis coll., 26/VIII/1962.

Body scales consisted of 19-19-15 rows of dorsals, smooth, with one apical pit; 150, 148, 151, 137 and 143 ventrals respectively; anal entire; 47, 43, 46, 39 and 51 paired subcaudals respectively; 2 internasals; 2 prefrontals; frontal as large as the ocular diameter; nasal divided; loreal present; 1-1 preocular (3-3 in EBRG 1136); 2-2 postoculars (3-2 in EBRG 1136); 1+2/1+2 temporals (2+3/2+3 in EBRG 1136); 8-8 supralabials (8-9 in EBRG 1574); 4th and 5th supralabials in contact with the eye (3rd and 4th left side in MBUCV 1665, 5th and 6th left side in EBRG 1574); 10-10 infralabials (10-11 in EBRG 1574); 2 pair chin shields, anterior pair (in EBRG 1136 divided anteriorly) longer than the posterior pair, and in contact with the first five infralabials (six first left side in EBRG 1574); maxilla with 15+2, 16+2, 18+2, 13+2 and 16+2 teeth respectively, the two posterior ones elongated, nongrooved, and separated from the rest by a diastema. The cephalic coloration consists of a pair of wide supraocular bands that run obliquely to neck; latter bands creamish, edged with black; dorsum of head greyish brown with small darker spots; lateral brownish postocular band present; supralabials creamish, with fine spots and dark lines on sutures (especially under eye); infralabials and gular region creamish, with several brown spotted sutures, especially toward anterior region of head; dorsum has 15 (16 in MHNLS 7680) brownish, black edged bands of five to six scales in length, separated by lighter spaces delimited by light grey; dorsum of tail with 4 dark bands similar to dorsals (3 in MBUCV 1665 and not definite in EBRG 1136). Venter laterally with numerous dark brownish to blackish spots which resemble rings of two to three scales, but are substituted by a less pigmented area toward midline (EBRG 1136 has rings only in contact zone with dorsals, and has many brownish small spots on entire venter); tail less pigmented than venter.

Body measurements (Total length, snout-vent length; in mm): MHNLS 7680 (265,227); MBUCV 1665 (535,467); EBRG 1574 (222,190); EBRG 1136 (590,498); MBUCV 8092 (763,632).

The material examined undoubtedly belongs to the subspecies *rhabdocephalus*, and its morphological characteristics generally fall within the range of variation found by Dixon and Soini (1977) for the subspecies in the Peruvian Amazonia. The genus *Xenodon* is now represented in Venezuela by two species, *X. severus* (Linnaeus), broadly distributed in almost all the country (Roze, 1966; Lancini, 1979), and *X. r. rhabdocephalus* (Wied), whose preliminary distribution had been indicated here. Previously, *X. r. rhabdocephalus* was known in Central America and South America south to Bolivia and Brasil (Peters and Orejas-Miranda 1970). Hoogmoed (pers. comm.) has also examined some specimens from Guyana, Surinam and French Guiana.

I thank E. Williams (MCZ), A. Lancini (MCNC) and F. Bisbal (EBRG) for the loan of material from their collections; W. Heyer provided me with information about specimens from USNM; M. Hoogmoed gave museum data of specimens deposited in Europe; J. Dixon critically read the manuscript.

REESTABLISHMENT OF THE COQUI, *Eleutherodactylus coqui* THOMAS, IN SOUTHERN FLORIDA

The leptodactylid frog, *Eleutherodactylus coqui* Thomas, is endemic to Puerto Rico where it is common and widespread at low and middle elevations (Thomas, 1965). It occurs in a variety of habitats, finding shelter in leaf axils, litter, tree cavities, and bromeliads. The coqui has been introduced into southern Florida, primarily in Dade County, on several occasions (King and Krakauer, 1966; G. Hendrix, pers. comm.), but did not become established until it was introduced at Fairchild Tropical Garden in South Miami (Austin and Schwartz, 1975). This population persisted for several years without dispersing from the site of introduction. It was apparently extirpated by a severe freeze in January, 1977 (Wilson and Porras, 1983). In this note, we report the reestablishment of *E. coqui* in Dade County, and we discuss the method of introduction.

In 1976, a bromeliad nursery on SW 304th Street in Homestead began to import bromeliads from Puerto Rican nurseries in Rio Piedras and Mayaguez, both low elevation locales, and in Aibonito, a mountain town at mid-elevation. Nursery stock from Puerto Rico is shipped via containerized cargo trailers, cooled to 18°C, to southern Florida ports. The cargo trailer is driven to the nursery site where it is unloaded. Unlike nursery stock from other tropical countries, stock from Puerto Rico is not fumigated to kill potential pests that might accompany the shipment. When plants are unloaded at the nursery, a variety of live animals often emerge with the plants. Such shipments may be a source of introduction for a variety of exotic animals into southern Florida.

Male coquis were first heard calling at the Homestead nursery in 1977, and this population has increased and persisted to the present. We have monitored this population for several years. Two voucher specimens (UF 54087; UF 54088) have been deposited at the Florida State Museum, Gainesville, and their identities as *E. coqui* confirmed (P. Meylan, pers. comm.). On most nights, it is possible to hear dozens of males calling within the nursery, so that the total population must number in the hundreds. The population is maintained in part by frequent importations of plants from Puerto Rico that bring in additional frogs. However, some degree of on-site reproductive input also occurs because we have observed coquis with egg clusters on five separate occasions.

In addition to the Homestead nursery, other bromeliad growers in the South Florida area also import stock from Puerto Rico. We have confirmed the presence of *E. coqui* at nurseries on SW 258th Street, SW 248th Street, and possibly SW 80th Street. Coquis have also been dispersed deliberately by nursery employees who have released them at their homes, and by accidental transport in bromeliads sold by the nurseries.

Although *E. coqui* has occurred in the Homestead area since 1976, it has not moved far from the sites of introduction. The immediate surroundings are suburbs set in pineland that is dominated by slash pine *(Pinus elliottii)* and various understory shrubs and grasses. Southern Florida is subject to a prolonged dry season in winter and spring, and experiences occasional freezes during some winters (Wilson and Porras, 1983). We believe, based on the environmental requirements of *E. coqui* in Puerto Rico (Pough et al., 1983), that exposure to droughts and freezes in southern Florida would be lethal to coquis. The coqui has survived seven dry seasons and several severe freezes at the Homestead nursery where overhead sprinkling moderates the effects of such perturbations. The lack of dispersal from nurseries provides evidence that natural southern Florida habitats do not provide conditions suitable to survival of *E. coqui.* The coqui seems unlikely to disperse naturally in southern Florida, but it will probably persist there in nurseries and similar areas in which it is protected from cold and dessication.

THE NORTHWESTERN LIMIT OF DISTRIBUTION OF *Rhineura floridana* WITH COMMENTS ON THE DISPERSAL OF AMPHISBAENIANS

New locality records extend the known range of the amphisbaenian *Rhineura floridana* across the Suwannee River, an important zoogeographic barrier, and suggest a mechanism for insular distribution of amphisbaenians. *Rhineura floridana* inhabits well-drained soils throughout much of northern peninsular Florida. Recent accounts of its distribution (Gans, 1967; Zug, 1968) shows its northwesternmost occurrence to the south and east of the Suwannee River.

A single *R. floridana* (UF 39647) was collected in Hamilton County, ca. 19.2 km by road NE White Springs. This locality is more than 25 km N of the previous northernmost record, at Lake City, Columbia Co., and lies north and west of the Suwannee River. It extends the known range of *Rhineura* to within 18 km of the Georgia border and makes the single record from Georgia (MCZ 4655; Georgia, no specific locality) more credible.

Previously, the westernmost collecting locality for *Rhineura* was Seahorse Key, Levy Co., Florida (Zug, 1968). A new, more westerly

Figure 1. Locality records for *Rhineura floridana* along the Suwannee River. New records represented by triangles, existing records represented by squares. Shaded area indicates regions of well-drained soils (Caldwell and Johnson, 1982). The records for Seahorse Key and Sumner occur on isolated Pleistocene dunes. The stippled portion of the inset map represents the overall range of *Rhineura*.

locality is 3.2 km S Jena, Dixie Co. (UF 39648), 40 km west of the Suwannee River (Fig. 1).

Eleven other specimens of *Rhineura* were collected in the area between the Jena and White Springs localities during April 1973, during a major flood of the Suwannee River. One specimen (UF 39649) was taken ca. 1.6 km south of the Suwannee River, near the town of Suwannee Springs (Suwannee Co.). Ten others (UF 39650-39659) were collected from long-leaf pine/turkey oak scrub on the south side of the Suwannee River, about 5 km north of Alton, Lafayette Co. All eleven *Rhineura* were found dead in quiet waters in recently flooded areas, apparently drowned. None was seen swimming.

It seems likely that amphisbaenians in general may not swim or do so very poorly. Gans et al. (1965) and Broadley et al. (1976) found amphisbaenians of two other genera, *Ancylocranium* and *Monopeltis*, drowned in shallow water. Laboratory tests with a living *Rhineura* (Meylan, unpublished observations) indicate complete inability to swim. An *Amphisbaena manni* sustained lateral undulatory locomotion in water and this species could be called a weak swimmer.

Although *Rhineura* apparently does not swim, overwater dispersal might occur by rafting. However, expatriation by rafts from the sandy, friable soils in which these burrowers live seems unlikely. The possibility that amphisbaenians are transported within floating logs or stumps seems unlikely, too, because they are truly fossorial. I have found only one record of amphisbaenians occurring in logs (Hoogmoed, 1973). In that account the logs were so rotten they could hardly be expected to float. Thus, swimming and rafting do not appear to account for the dispersal of *Rhineura* across water. Other more plausible explanations are available. *Rhineura* could have reached the island of Seahorse Key, FL, during periods of glaciation, when ocean levels were far lower than at present, and the island was contiguous with the mainland. The presence of *Rhineura* on both sides of the Suwannee River can best be explained by changes in the course of the river through time. Stream capture and water diversion, as well as natural bridge formation, are frequent in the karst topography of northern Florida (Vernon, 1951). It is likely that the Suwannee has not long occupied its present valley, but flowed through what is now the Waccasassa Flats and entered the Gulf of Mexico where the Waccasassa River does today (White, 1970).

The data presented here suggest that *Rhineura floridana* is not well disposed to dispersal across water. Its distribution in northwest Florida is best explained in terms of historical changes in the land surface rather than the ability of this species to disperse. The admittedly limited evidence indicates that amphisbaenians in general may have limited overwater dispersal capabilities. If these findings can be corroborated, a land-bridge or vicariant origin for amphisbaenians on islands would be suggested.

ACKNOWLEDGMENTS

TECHNIQUES

A METHOD FOR NOCTURNALLY LOCATING LIZARDS

Locating animals for nocturnal observations is often difficult. In order to monitor the nightly activity of the ringtail *(Bassariscus astutus)* Trapp (1972) utilized a microlamp collar consisting of a "grain-of-wheat" lamp plus four disc batteries connected in parallel and inserted into the transparent sleeve of a plastic medical bracelet. Jackson (1959) introduced and Phinney et al. (1967, 1969) elaborated upon the use of fluorescent pigment to mark and relocate large numbers of fish. The pigments used by Phinney (1967) consisted of a solid solution of fluorescent dyes in a melamine-sulfanamide-formaldehyde resin. This mixture was sprayed upon the fish using a compressed air gun and subsequent relocation of the animals was made through the aid of ultraviolet light.

Each of these methods is certainly an effective means of marking and relocating animals under dim or dark light conditions. However, neither method would work satisfactorily when applied to small reptiles since a collar with lamps and batteries would be far too heavy and the application of fluorescent dyes requires a mucous covered skin. Here we describe a novel method of marking small reptiles which does not require batteries, lamps or moist skin and is not only effective but procedurally simple.

While determining the nocturnal locality of adult anoline (*Anolis* sp.) lizards in Puerto Rico, 20 individuals were marked, released and subsequently relocated using Cyalume® lightstick (American Cyanamid Company, Bound Brook, New Jersey) a phospho-luminescent liquid. Activated Cyalume® was extracted from its sealed plastic container using a hypodermic syringe and 23 ga. needle. The liquid was then injected into 1.8 x 30 mm micropipette sections, one end of which was sealed with Seal-Ease® (Clay Adams, Parsippany, New Jersey) tube sealer. The other end was similarly sealed following tube filling. Experimental animals were captured and marked with these glowing tubes between one-and-a-half and two hours before nightfall. Duco® cement (E. I. du Pont de Nemours

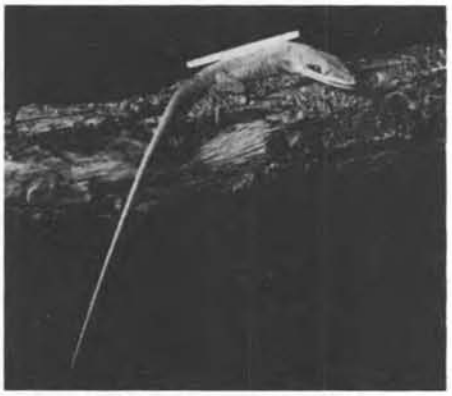

Figure 1. Adult anoline lizard with glowing tube attached to dorsum.

and Company, Inc., Wilmington, Delaware) was used to attach each tube longitudinally to the lizard's dorsum (Figure 1); the glue was allowed 5 minutes to dry, after which the animals were released. In the remaining light hours lizards were observed interacting normally with no apparent behavioral restraints due to the marking device (Figure 1). Approximately 2 hours after nightfall individuals were easily located at their perch sites from a distance of up to 30 m., and individuals could be located as late as 6 hrs after nightfall.

This method is apparently harmless to the animal since in all cases the device was sloughed off in 24 hrs. with no visible damage to the lizard's body. This method of marking small lizards could be applicable to other reptiles. Larger lizards and snakes could be similarly marked and more than one glow tube could be used for individual identification.

Funding was provided in part by a Sigma Xi Grant-in-Aid of Research to DC, and FRCE Grant No. 4-22165 to JG. We wish to thank A. Estrada and J. Alvarez for assistance throughout this study.

A "NEW" LIVE TRAP AND A COMPARISON WITH A PIT-FALL TRAP

Amphibian and reptile live traps are legion (Thomas, 1977; Scott, 1982). Because of economic and time constraints inherent in a recent study of herpetofauna populations in the Lower Coastal Plain of Mississippi, we had to design a trap that was efficient in capturing the smaller, more secretive herpetofaunal elements and could be easily and inexpensively constructed.

Basically the trap is of the funnel-trap type (hereafter called a "pipe-trap"). It is light in weight, fairly rigid, and easy to store. We constructed the pipe-traps with the intent of capturing small animals and excluding larger ones. The pipe-trap (Figure 1) consisted of: (1) a cylinder of aluminum window screening, (2) three disks of plywood or fiberboard, (3) a short length of lath, and (4) a short length (about 20 cm) of 1.9 cm (internal diameter) PVC pipe. The front and second disks and the lath were stapled to the screen cylinder. Cost per trap (in 1981) was about 75 cents if all new material had been used.

Our pipe-traps had a diameter of 15 cm (6 in.) and a length of 51 cm (20 in.). To remove captured animals, the wire was unfolded from around the rearmost disk, the disk removed, and the animals were shaken out or removed by hand through the access port in the second disk. Snakes that appeared to be too large (especially *Coluber constrictor priapus* and *Lampropeltis getulus holbrooki*) to enter the pipe were commonly captured.

The traps were used in conjunction with drift fences made of 61 cm x 20 m (1981) and 61 cm x 40 m (1982) strips of heavy vinyl sheeting. Approximately the lower 10 cm of the strips were buried. In 1981 the top edge of the strips was stapled to angled stakes so that only the top edge was in contact with the stakes. In 1982 heavy (70-100 lb. test) monofilament fishing line was stretched from end support stakes and the vinyl strips were taped or riveted to these lines. This latter methodology was superior. In 1981 the layout of the fencing and traps was of the standard "V" pattern. In 1982 the layout was changed to a "W" pattern and two pitfall traps (25 cm diameter, 30 cm deep plastic trash containers) were incorporated into the design with one pitfall and one pipe trap used at each end of the "W". In both years additional 61 cm x 1 m vinyl strips were used at both ends to funnel animals into the traps. For pipe-traps a shallow trench was dug behind the vinyl sheeting so that when the pipe-trap was laid in the trench and the pipe pushed through a hole in the sheeting the pipe was flush with the ground. Earth was tamped around the juncture of pipe and sheeting. Animals were evidently funneled by the sheeting to the pipe opening which they entered, crawled through, and then fell into the trap. The cage part of the pipe-traps was covered with vegetation to reduce desiccation mortality of trapped animals.

Table 1. A comparison of black versus white PVC pipe in terms of herptiles captured in 420 trap-days in southern Mississippi in 1981.

Order	Total Number Captured	Number Per Trap-Day	Number Captured in Traps With PVC Pipe Colored: Black	White
Caudata	9	.021	7	2
Anura	7	.017	4	3
Squamata	104	.248	75	29
Suborder Lacertilia	89	.212	63	26
Suborder Serpentes	15	.036	12	3
Total Captures	120	.286	86	34

Table 2. A comparison of pit-fall traps and pipe-traps in numbers of herptiles captured versus the number expected (3/5 of the traps were pipe traps) in southern Mississippi in 1982.

Order	Total	Captures of Herptiles: Pipe-Trap OBS.	Pipe-Trap EXP.	Pit-fall OBS.	Pit-fall EXP.
Caudata	23	19	14	4	9
Anura	45	13	27	32	18
Squamata	515	425	309	90	206
Suborder Lacertilla	447	366	268	81	179
Suborder Serpentes	68	59	41	9	27
Total Captures	583	457	350	126	183

In 1981 total effort was 420 pipe-trap days from 1 April to 30 June. In 1982 we trapped from 1 March to 7 September (except for 9 July to 18 August when hot weather necessitated closing the traps) for a total of 12,060 trap days (7236 pipe-trap and 4824 pit-fall trap days). In both years we trapped equally in habitats ranging from mesic hardwood bayheads to xeric pine uplands.

In 1981 we used both white and black colored PVC pipe equally for the pipes. Pipe-trap captures were not equal (Table 1). More salamanders, lizards, and snakes were captured in pipe-traps with black pipes [χ^2 (Caudata, Anura, Lacertilia, Serpentes) = 23.4, $P<.001$]. Only the toads (*Bufo* sp.) showed little difference and this might be attributed to a small sample size (n = 7). We hypothesize that the black PVC pipe may act as an attractor by more closely simulating an earthen hole than white PVC pipe.

In 1982 we used only black PVC pipe in the pipe-traps. The increased trapping effort resulted in many more herptile captures (Table 2). When corrected for the disparity in numbers of trap types employed (3/5 were pipe-traps), capture rates between pipe-traps and pit-falls were not similar (Table 2). All observed numbers of captures differed significantly from the expected (χ^2 Caudata = 4.6, $.05>P>.025$; χ^2 Anura = 18.1, $P<.001$; χ^2 Lacertilia = 89.5, $P<.001$; χ^2 Serpentes = 19.9, $P<.001$). Salamanders, lizards and snakes were more likely to be captured in the pipe-traps whereas frogs and toads were much more likely to be captured in pit-fall traps. The difference in trapability is probably a reflection of behavior differences. Salamanders, lizards, and snakes are probably more prone to entering burrows than frogs and toads. The "hopping" type of locomotion by anurans may make them more apt to land in a pit-fall than the more dexterous sala-

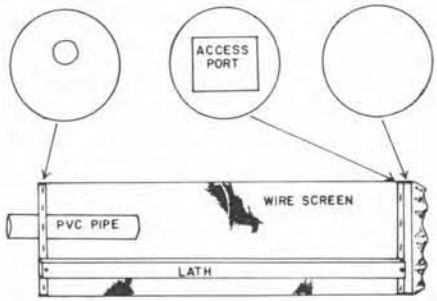

Figure 1. Drawing showing the component parts of the live trap and the sequence of plywood disks.

manders and lizards. Also, the pipe-traps caught large numbers of insects which remained alive and these may have acted as bait, especially for lizards.

We thank E. Harrison and H. Pearson for comments on an early draft of this manuscript. Data were collected during the course of cooperative agreements 40-7B82-1-22291 and 40-7B82-2-22248 with the U.S. Forest Service, Southern Forest Experiment Station, Range Management Research. This project was endorsed by the U.S. Man and the Biosphere Program (MAB-3) contributing to grazing land objectives. The assistance of the personnel of the Biloxi District Ranger Office, DeSoto National Forest, is again gratefully acknowledged.

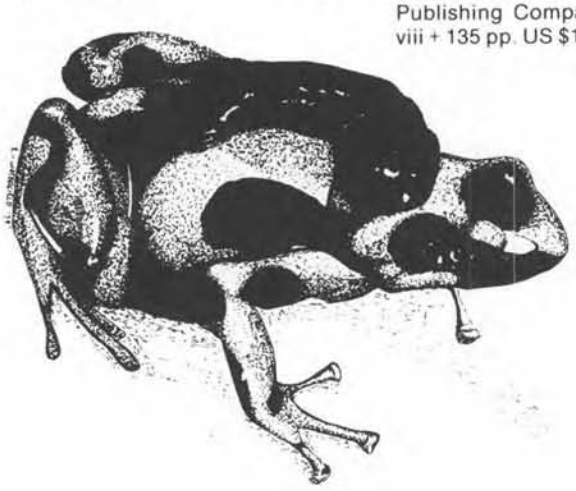
BOOK REVIEWS



Mammal-Like Reptiles and the Origin of Mammals, by T. S. Kemp. 1982. Academic Press. 363 pp. $49.50.

Although the synapsids have been extinct for more than 190 million years, a remarkably detailed fossil record of them remains. The first members of the group date from the Lower Pennsylvanian, more than 300 million BP and in the course of their history, radiated widely to become for a time dominant members of the terrestrial fauna. The pattern of evolution of these mammal-like reptiles consisted of three phases: adaptive radiation of the pelycosaurs through the early Permian; radiation of the non-cynodont therapsids in the late Permian; the Triassic radiation of the cynodonts. Each of these three radiations commenced from a single lineage that had originated during the previous phase and followed a broadly comparable course. The fact that many features of the evolutionary pattern occurred independently three times in succession implies to the author that there may be underlying rules governing the process of macroevolution.

This fascinating story is spelled out in detail by a comprehensive description of the fossil record, showing step by step the steady accumulation of mammalian features that eventually became integrated into the mammal. Kemp discusses those structures and processes which do indeed characterize a mammal and the means by which this homeostatic complex could have developed. There are 117 figures in the book, most of which depict the skull, postcranial skeleton, teeth, or other features that are of significance. A revealing book for those who have not kept up on their palaeoherpetology.

Herpetology of Europe and Southwest Asia: a Checklist and Bibliography of the Orders Amphisbaenia, Sauria and Serpentes, by Kenneth R. G. Welch. 1982. Robert E. Krieger Publishing Company, Malabar, Florida, vii-viii + 135 pp. US $14.50. ISBN 0-89874-533-0.

As Mertens & Wermuth's (1960) Die Amphibien und Reptilien Europas becomes more and more outdated, a modern treatment of the European and adjacent herpetofauna is most welcome.

Unfortunately the main title of Welch's publication on Europe and Southwest Asia promises more than what it keeps: neither the amphibians nor the other orders of reptilia (Testudines and Crocodylia) are treated. For those who have a professional interest in the area mentioned and who are to work in the future in herpetological systematics, the book is an essential publication. However, it must be used with great care and reservation: this as a serious warning to uncritical readers.

The publication is apparently aimed at those who have no ready access to scientific libraries where such standard publications as "Das Tierreich," the "Zoological Record" or the "Handbuch der Reptilien und Amphibien Europas" would be available, and it contains 18 chapters, two appendices, a bibliography, two indices (one to genera and one to species) and subspecies, and the acknowledgements.

Chapter one gives surprisingly little information about the area covered, without a map, and similarly short is the information on the classification followed. With the acknowledgements I miss indications to the scientific institutions the author was associated with.

The check-list is arranged according to families, the taxa in alphabetical order. The distribution data are sometimes vague: with *Elaphe longissima longissima* the account does not indicate that it occurs in West Germany (Schlangenbad, Passau (Mertens & Wermuth, 1960)). The distribution of *Chamaeleo chamaeleon chamaeleon* lacks Portugal (Crespo, 1972), Sicily (u.a. Schreiber, 1912) and Kreta (Wettstein, 1953).

The bibliography (pages 92-126) contains many titles about behaviour, pathology, parasitology, physiology, toxicology and vivarium-keeping, which have no direct context. On the other hand, there are several major regional publications missing: u.a. Europe (Schreiber, 1912; Mertens, 1972,) Austria (Luttenbergger, 1978) Balearic Islands (Eisentraut, 1950), Spain (Salvador, 1974), Switzerland (Stemmler, 1981), Turkey (Baran, 1976, 1978). The publication by Boehme (ed.) 1981 apparently is too recent to have been considered for inclusion in this book.

Several monographic treatments are also missing from the book: Anguidae (Petzold, 1971), *Natrix natrix* (Kabisch, 1974), Elapidae, Hydropheidae, Viperidae and Crotalidae (Klemmer, 1963), and *Vipera berus* (Frommhold, 1969). The student of the unique Lacertid fauna of the many islands and islets in the Mediterranean will be surprised to find that list incomplete, for example: Lanza (1976), Lanza, Adriana & Romiti (1971), Lanza & Capolongo (1972), Lanza & Brizzi (1974, 1977), Brizzi & Lanza (1975) are not covered.

More careful proofreading would have been most beneficial, especially within the bibliography.

The bibliography is thus by no means a comprehensive treatment of the Herpetofauna of Europe and Southwest Asia, but a very important step forward towards a more mature

version. The relatively low price and the neat professional presentation of the book may induce many professionals and amateurs as well to buy their copy.

A Review of the Colubrid Snakes of the Genus *Tantilla* of Central America, by Larry David Wilson, 1982. Milwaukee Public Museum Contributions in Biology and Geology, No. 15. [ii], 77 pp., 23 figs., 6 tables. Available from the Milwaukee Public Museum, 800 West Wells St., Milwaukee, Wisconsin, 53233. $10.00, plus $1.00 for shipping and handling. A 10% discount offered to libraries and institutions.

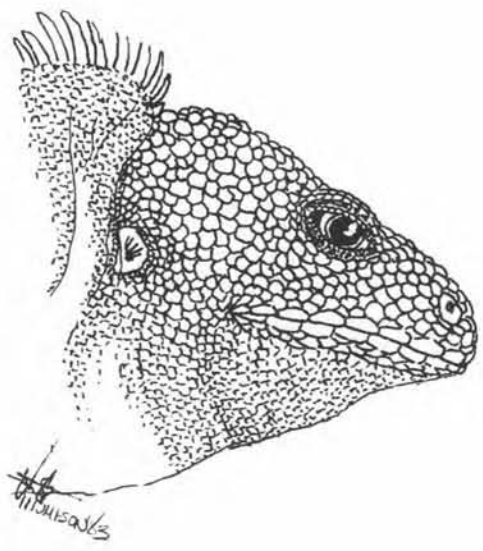
". . . traditionally considered to contain species difficult of identification," *Tantilla* has been the focus of attention for some 14-15 years by Larry David Wilson, whose first contribution to knowledge of the genus appeared in 1970. Since then a dozen or so accounts have been undertaken, of which the present is the most recent to be published and the most voluminous.

Monographs are always welcome, and the expected revision of *Tantilla*, for which the present article is a prelude, is exemplary, for the genus has been in a somewhat chaotic state despite its wide distribution throughout most of the continental Americas and its numerous taxa, numbering some 48 species according to Wilson - the second-most speciose (to *Atractus* with some 70 species) genus of snakes in the Western Hemisphere.

The difficulty of the genus, taxonomically, is not so much a matter of inherent problems of reliable correlation of phenotype with gene pool but of (1) inadequate material (many species are quite rare in collections), (2) premature (hence inaccurate) extrapolations from scant material (of which the present reviewer is as guilty as anyone else), and (3) the inevitable bias derived from published accounts.

Wilson is ideally suited temperamentally for sane screening of information now accessible on the annoyingly controversial species of this genus. As thoroughly documented by the present article, all materials known to exist in collections anywhere in the world have been exhaustively ferreted out and their conventionally studied characters recorded; hence the problem of inadequate samples has been diminished although not eliminated. In addition, Wilson has viewed his massive accumulation of data with a coldly impassive eye (not always true of previous workers), drawing conclusions only as overwhelmingly justified.

Thus the taxonomic treatment in the present account is conservative but thoroughly sound as far as it goes, admitting no subspecies and no species that are not clearly substantiated. Order is restored to serve as a secure basis for future work with larger and more geographically representative samples.



Summarizing knowledge of all 17 Central American species of the genus, the review is the final authority for that entire region, and also has an important bearing upon understanding of the adjacent faunae of Mexico and South America. A key to the species, and for each species a description, summary of variation, spot distribution map, list of specimens, localities, synonymy, illustrations of total appearance, scutellation or pattern, brief notes on natural history, and tabular comparative summaries of variation are given. It is a model review, seemingly leaving little for the projected generic monograph save theoretical considerations of phylogeny and relationships.

The most startling conclusion is that *T. alticola*, until 1977 (when Wilson et al. reported it from Costa Rica) thought to be restricted to Colombia, actually occurs as far north as Nicaragua and is a senior synonym of *T. costaricensis*, as well as the Colombian *Homalocranium coralliventre* and a lectoparatype of *T. jani*.

Another major alteration of current concepts is the rejection of all of the several subspecies of *T. schistosa* previously recognized, including *phrenitica* and *taylori*, on grounds of over-riding variation. Finally, two new species, *T. cuesta* and *T. excubitor*, both from Guatemala, are described as new. Thus Wilson has authored, or shared authorship (with Mena) of three valid Central American species of *Tantilla*—more than any other author (Barbour 1, Bocourt 2, Boettger 1, Boulenger 1, Cope 2, Günther 2, Hallowell 1, Linnaeus 1, Mertens 1, Smith 1, Stuart 1), although the roster approaches a catalog of workers in Central American herpetology.

The revision is indispensable for anyone working with *Tantilla* or with the herpetofauna of Central America. It will vastly simplify evaluation of new material from that area.

Lizards in Captivity, by Richard H. Wynne. 1981, 189 pp., ill. $7.95. THF Publications, Inc., P.O. Box 427, Neptune, N.J. 07753-0427.

This book attempts to provide the amateur enthusiast with factual, readable information on the diversity of lizards and their care in captivity. The book contains an abundance of interesting photos, including 58 color and 67 black-and-white illustrations. There is a brief introduction, a general description of lizards, and a list of families. Nineteen families are recognized, and one or more species or genera from each family are dealt with briefly. Each account contains the common name, scientific name, distribution, length, description, habitat, type of cage, temperature range, food and water, special needs, young, and related species. The accounts comprise about 95 pages of text. In addition, there are notes on housing, food and nutrition, care of young and eggs, diseases, field work, and a glossary and bibliography.

While the objectives of this book are laudable and in large measure fulfilled, there are inaccuracies and inadequacies which could mean the difference between success and failure for the amateur lizard lover. Therefore, these shortcomings warrant consideration.

One of the most frequent causes of failure in maintaining lizards in captivity is the lack of an appropriate thermal environment (Avery, 1979). Wynne attempts to forestall this problem for the novice by including the preferred temperature range in each generic or species account. I took Wynne's temperature data from ten accounts, converted Fahrenheit to Centigrade, and compared this information with corresponding data in Brattstrom (1965) which were collected in nature. In all cases, Wynne's upper temperature limit falls below the maximum voluntary temperature for the species in Brattstrom. In two cases *(Iguana* and *Crotaphytus),* Wynne's value is nearly 10 degrees below that recorded by Brattstrom. Moreover, in six cases *(Basiliscus, Crotaphytus, Dipsosaurus, Gambelia, Iguana* and *Ophisaurus)* Wynne's upper value is less than the mean preferred temperature for the species calculated by Brattstrom. Wynne does not mention a source of information for his temperature data. Comparative data probably exist for some of the other, more exotic species treated in the text, but I made no attempt to search the literature. Suffice to say that some of Wynne's other preferred temperature ranges are suspect.

The disparity between Wynne's recommended temperatures and those apparently preferred by lizards in nature is a matter of concern. Moreover, the preferred temperature of a lizard will vary as a function of the state of digestion, reproductive condition, general health, and perhaps other factors as yet not identified (Regal, 1980). The solution to this problem is obvious and simple: create a thermal gradient by suspending a heat lamp of suitable wattage at one end of the cage. Such a gradient will enable the lizard to voluntarily find its optimum temperature as dictated by its changing physiological state.

Wynne points out the need to provide captive lizards with a source of ultraviolet light (p. 154) when kept indoors. He recommends the use of special bulbs designed for houseplants and home aquaria. However, Regal (1980) states that "Gro-lux" lights, commonly used for houseplants, are not effective. Unfortunately, Wynne does not mention "Vita-Lite" (Duro-Test Corp.) which has been a recommended product in several studies dealing with maintenance of captive lizards.

Wynne advocates maintaining captive lizards outdoors (p. 149), but neglects to caution the hobbyist about several problems. Space, time, and money are required to build a proper outdoor facility. Adequate shelters must be provided to protect lizards from unexpected frosts, torrential rains, and high temperatures. Rarely do these shelters duplicate the protective microenvironment afforded by deep burrows which in nature permit desert species to escape thermal extremes. Consequently, captive lizards may become stressed and die as a direct or indirect result of exposure. An outdoor facility must also be dog and cat proof as these animals roam some neighborhoods at will. The aforementioned factors pose serious problems for the novice and experienced collector alike.

Wynne makes recommendations on how to breed lizards in captivity (p. 159), but these are inadequate as far as temperate zone species are concerned. He prescribes an abundance of food rich in calcium and vitamins, a simulated natural habitat, and minimal disturbance. I agree. However, many experienced hobbyists are well aware that hibernation (brumation) is usually essential to bring temperate zone lizards into breeding condition in spring. Wynne fails to mention, let alone discuss, the importance of winter dormancy to successful captive propogation. Facilities to hibernate lizards are not always available to the amateur. However, a basement or unheated room in the house has often proved satisfactory.

Although Wynne considers diseases and their treatment (p. 165), he neglects to mention several rather common ailments caused by bacteria, including respiratory infections, enteritic infections, and salmonellosis. *Salmonella* is especially important since it is considered a potential human pathogen (Marcus, 1971). Amateur hobbyists would have benefitted greatly if Wynne had cited one or more references on disease treatment such as Murphy (1975), for example. Wynne discusses calcium-phosphorus imbalance, which he calls "rubber jaw." However, novice owners of *Iguana* and *Ctenosaura* might not be alerted to the problem since in these iguanines the initial symptoms usually are swollen limbs and tail. The owner is reluctant to believe that anything is wrong with his pet except that it may be fed too much.

Wynne suggests the use of moist earth or sphagnum moss to hatch lizard eggs (pp. 160-161). How moist is moist? That may depend on the species. Wynne should have encouraged the hobbyist to experiment with measured proportions of water and hatching medium to obtain the highest possible hatching success.

A few minor annoyances caught my eye, such as the notion that mealworms "clog the intestines" (p. 156), and that earthworms may comprise the natural diet of *Corytophanes* (p. 55).

Finally, it is unfortunate that this book did not discuss conservation. In fairness, Wynne does indicate the endangered status of some *Cyclura* (p. 49), and urges the collector (p. 177) to never overcollect. However, the author could have done more (without increasing pages) by noting those forms (e.g. *Heloderma, Phrynosoma*) that have state and/or federal protected status. Wynne should have encouraged collectors to contact state wildlife agencies concerning lizards and the law. Also, as measures to minimize the impact of collecting, Wynne could have urged collectors to treat the microhabitat with care and to collect juvenile lizards rather than reproductive adults.

In sum, this is an interesting and stimulating book for the amateur, but unfortunately it lacks substance and accuracy in places. I hope the author will consider my critical comments should he contemplate a revised edition.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

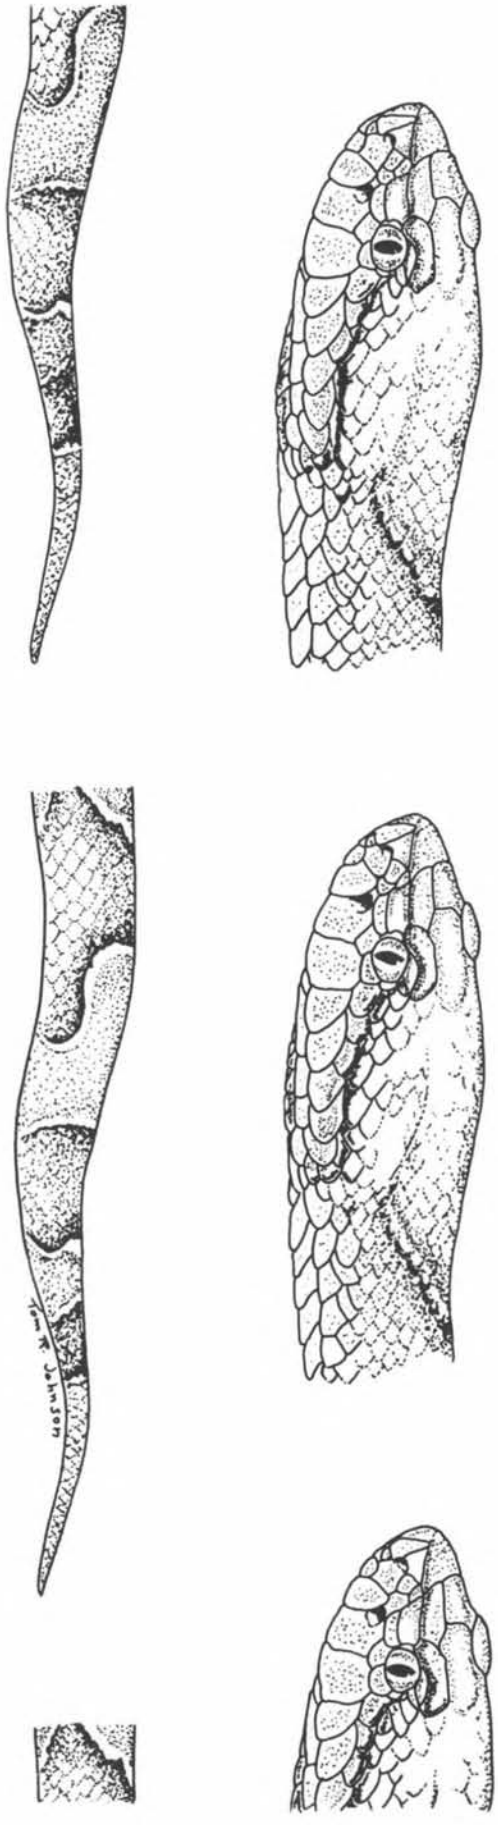
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1983

Student member	$15.00*
Regular member	$18.00*
Sustaining member	$30.00
Contributing member	$50.00
Institutional	$30.00*



***Non-U.S. members and institutions must also include $5.00 additional. This surcharge is to help defray higher mailing costs.**

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

MEETINGS 105

FEATURES
Herpetological activities in the People's Republic of China, by K. Adler 107
A leatherback returns to Flagler County, by V. A. Nichols and C. H. Dutoit 107
An inventory of phenotypic abberancies in the Eastern Diamondback Rattlesnake (*Crotalus adamanteus*), by F. B. Antonio and J. B. Barker 108
Another specimen of *Anarbylus*, by E. S. Benes and D. P. Moth 110
A sea turtle nesting at Island Beach State Park, Ocean County, New Jersey, by R. L. Brandner 110
Least sandpiper predation on *Bufo americanus* and *Ambystoma maculatum* larvae, by P. W. Stangel 112
Terrestrial movements of an Eastern Tiger Salamander *Ambystoma tigrinum*, by R. D. Semlitsch 112
A character for differentiating the sympatric lizards, *Anolis cooki* and *Anolis cristabellus*, D. L. Marcellini and T. A. Jenssen 113

TECHNIQUES
An additional restraint technique for venomous snakes, by P. S. and M. G. Freed ... 114
A simple restraining device for large turtles, by D. A. Galbraith and R. J. Brooks 115
A technique for partitioning hatching and mortality estimates in leaf-breeding frogs, by M. D. Hayes 115

NEWSNOTES 117

LIFE HISTORY NOTES 118

GEOGRAPHIC DISTRIBUTION
New Records 122
First specimen of *Ambystoma tremblayi* for Algonquin Park, Ontario, by D. J. Mountjoy 124
The status of *Clemmys muhlenbergii* (Schoepff) in Connecticut, by M. W. Klemens and J. L. Warner 124
Update on the list of amphibians and reptiles known from Honduras, by L. D. Wilson 125

BOOK REVIEWS
Japan's Schlangen (Volume 1), reviewed by C. J. McCoy 126
Dinosaurs, Asteroids and Superstars: Why the dinosaurs disappeared, reviewed by G. R. Pisani 126
Lizards of Western Australia I. Skinks, reviewed by H. C. Seibert 126
A guide to field identification - reptiles of North America, reviewed by L. D. Wilson 127

SSAR BUSINESS

MISCELLANEOUS NOTES FROM THE TREASURER

1. Members living outside the United States and not having direct access to U.S. currency may now pay their dues on their VISA or MASTERCARD accounts. Simply send to the Treasurer your account number (in full) plus expiration date and the dollar amount to be charged.

2. We have members and would-like-to-be members who reside in countries where foreign exchange is prohibited. Some of these members are already being supported by friends in the United States, but there are others who need a sponsor. Donations of $22 (student) and $27 (regular) will provide a year's membership.

3. The last set of Catalogue accounts includes an announcement of subscription renewal for the next set. This announcement is inserted in *all* packets and is simply a reminder. If you have already paid your Catalogue subscription together with your SSAR membership dues, there is no need to duplicate the payment! ●

EXHIBITORS WANTED FOR 1984 JOINT SSAR-HL-ASIH MEETING

On 28 July through 4 August 1984, the Herpetologists' League, the Society for the Study of Amphibians and Reptiles and the American Society of Ichthyologists and Herpetologists will be sponsoring a meeting at the University of Oklahoma in Norman, Oklahoma. This will be the largest such meeting ever held and will be the first joint meeting for these organizations in 5 years.

I have been asked by the local committee to locate possible exhibitors for this event and as such would be interested in being contacted by anyone who might wish to participate. The following information provides some details concerning the meeting:

Attendance expected: 1000
Registrants: Biologists, college professors, zoo and museum personnel, state and federal wildlife officials, graduate students in biology, serious lay persons with interests in fish, amphibians and reptiles.
Previous Exhibitors: Publishers, used book companies, biological supply companies, manufacturers of animal collecting and housing equipment, artists (with animal themes—especially fishes, amphibians and reptiles), tee-shirt sales, travel services.
Additional Appropriate Exhibitors: Veterinary products, photographic supplies (especially macro and telephoto for nature photography), teaching tools, and other supplies.
Exhibit Locations: In corridors adjacent to meeting rooms. Participants will be exposed to exhibits many times as they go to and from sessions.
Cost: $100 for each table (4x6 feet) or equivalent for space (up to 6x12 feet). Artists who sell materials created by themselves will be charged $50 or the equivalent in donated art or crafts; such persons are expected to be engaged actively in their work at the exhibit area.
Shipment and Care of Exhibits: Exhibits may be shipped (prepaid) in returnable containers to ASIH-HL-SSAR, c/o Department of Zoology, University of Oklahoma, Norman, Oklahoma, 73019 to arrive no later than 20 July 1984 with instructions for setting up. Exhibits will be returned (shipment collect) by 15 August 1984. Where possible, exhibitors are encouraged to have their exhibits attended by an employee who can bring the materials with them. Exhibitors in attendance will be charged a much reduced registration fee unless they plan to attend the free meals and social events.

If you are interested in exhibiting, please contact me at the address below.

Neil B. Ford, Ph.D.
Assistant Professor of Biology
(Exhibit Chairman: ASIH-HL-SSAR
Joint Meeting, 1984)
University of Texas at Tyler
3900 University Boulevard
Tyler, Texas 75701, U.S.A.
(214) 566-1471, Ext. 206 ●

PROPOSALS FOR ANNUAL MEETING SYMPOSIA OR WORKSHOPS

To be considered for approval by the SSAR/HL joint Meetings Committee, proposals for symposia, workshops, and other special presentations at Annual Meetings must be received by the Committee chair at least 18 months prior to 1 August of the year in which the program is to be held. Further information can be obtained from the Committee chair, Lynne Houck (Department of Biology University of Chicago, 1103 E. 57th Street, Chicago, Illinois 60637, U.S.A.). Proposals for the 1985 meetings are due by 1 February 1984. ●

SSAR THANKS ACADEMIC PRESS

Academic Press has enthusiastically supported our annual meeting for the past several years through financial contributions and donation of their herpetological publications. Their generosity has enabled addition and expansion of activities which have contributed immeasurably to the enjoyment of the meeting by all those in attendance.

SSAR expresses its gratitude to Academic Press for their continuing support of our meetings and the goals of our society. It is through such gestures that these meetings have become an international forum for the dissemination of herpetological information. ●

AUCTION ITEMS NEEDED

The 4th annual SSAR auction/social will be held in conjunction with the SSAR/ASIH/HL meetings at the University of Oklahoma, Norman, in 1984. The objects of the auction are to provide financial support to the local meeting committee while giving participants an opportunity to purchase auction items at bargain (?) prices while socializing in a convivial atmosphere.

In the past, most auction items have been books along with a few herp-oriented art objects (sculptures, paintings, photographs). These are all excellent objects to auction, but those wishing to donate for the affair at Norman might observe the following requests: 1) donate only *one* copy of a book (multiple copies are boring for bidders and the auctioneer), 2) consider donating *more* art objects, 3) consider donating tastefully humorous herp-oriented items, and 4) be sure to donate ichthyological (=fishes, for those with narrow herpetological interests) items out of consideration for the better half of the ASIH.

Please donate something. Bring it (them) to the meeting, or mail it (them) in advance to Victor Hutchison, Department of Zoology, University of Oklahoma, Norman 73019. Much thanks.

..... THE AUCTIONEER ●

1983 SSAR GRANTS-IN-HERPETOLOGY AWARDS

The Society for the Study of Amphibians and Reptiles is pleased to announce the following awards in the 1983 Grants-in-Herpetology Program:

GRADUATE STUDENT RESEARCH:

Paul J. Watson, Section of Neurobiology and Behavior, Cornell University. "Chemical communication and sexual selection in the red-spotted newt, *Notophthalmus viridescens* (Rafinesque)." $450.

Robert A. Newman, Department of Biology, University of Pennsylvania. "The genetic basis of traits affecting larval survival of *Scaphiopus couchi*, a desert anuran (Pelobatidae)." $275.

Joyce S. Tsuji, Department of Zoology, University of Washington. "Latitudinal comparison of thermal acclimation of metabolism in lizards." $250.

REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS:

Kevin N. Brewster, Wisconsin Herpetological Society. "Reptilian ecology of endangered prairie habitat in Wisconsin." $250.

Steve Hammack, North Texas Herpetological Society. "A pictorial guide to the amphibians and reptiles of Dallas and Tarrant Counties, Texas." $200.

HERPETOLOGICAL CONSERVATION:

Peter W. Stangel, Department of Zoology, University of Georgia. "A proposed study of the breeding biology and larval ecology of the spotted salamander, *Ambystoma maculatum*." $400.

SSAR extends it congratulations to all recipients of awards and encourages the submission of proposals for next year's program. SSAR also expresses its thanks to the 1983 Grants-in-Herpetology Committee, composed of: Linda R. Maxson (Chairperson), Robert Mount (Conservation Research), Malvin L. Skaroff (Regional Herpetological Society Projects), Donald C. Forester (Graduate Student Research), and Dale L. Marcellini (Herpetological Research in Zoos). ●

SSAR GRANTS-IN-HERPETOLOGY

The Society for the Study of Amphibians and Reptiles is pleased to announce that proposals are now being accepted for the 1984 Grants-In-Herpetology Program. This Program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. All applicants (or their advisor or sponsor) must be a member of SSAR. Grant proposals will be considered in the following areas:

1. GRADUATE STUDENT HERPETOLOGICAL RESEARCH. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only, with a letter of support from the student's major advisor or committee chairperson.
2. HERPETOLOGY-ORIENTED CONSERVATION. Proposals should address research on endangered or threatened species at the state, national or international levels, or address research or critical herpetological habitats. Proposals may be received from individuals only.
3. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address any herpetological research endeavor or project, provided said endeavor or project concerns herpetology within the implied geographic limits of the regional society. Proposals may be submitted by regional herpetological societies or by individual members of the society. If the latter, a sponsoring letter from the current societal president or an advisor should accompany the proposal.
4. HERPETOLOGICAL RESEARCH IN ZOOS. Proposals may address any herpetological research endeavor which is conducted at a zoo. A letter from the represented zoo or supporting institution should accompany the proposal.
5. FIELD WORK (Auto Mileage). Proposals may address any area of herpetological research and may be submitted by any member of SSAR. Funding will only be granted for expenses associated with auto travel for collecting (or observing) study animals. (Two awards of $215.)

Each proposal should include the following information: A) *Background & Objectives* of the proposed project, in terms of its relevance to herpetology, B) *Methods* of carrying out the research or conducting the project, C) *Budget for the project*, which should not exceed $430 in each category, and D) *Curriculum Vitae* and *Letter of Support* (if applicable). The proposal must be typed double spaced and must *not* exceed 5 pages, excluding cover page, abstract, budget, curriculum vitae, and bibliography.

Successful applicants will be expected to submit to SSAR a written report of their research or project, within a reasonable time after the project year is completed. They are also encouraged to submit for publication the results of their research or project, preferably to *The Journal of Herpetology* or *Herpetological Review*.

Members of the SSAR Grants-In-Herpetology Committee will evaluate all proposals, projects or programs. Committee members are: Linda R. Maxson (Chairperson), Robert W. Murphy (Graduate Student Research), John B. Iverson (Conservation), Malvin L. Skaroff (Regional Society Projects), James P. Bacon (Zoo Research), and Donald C. Forester (Field Work).

Individuals submitting proposals must designate to which of the five areas their proposal applies. All proposals must be typewritten and submitted in duplicate no later than *13 APRIL 1984 to:*

Dr. Linda Maxson
Department of Genetics and Development
University of Illinois
515 Morrill Hall
505 South Goodwin Avenue
Urbana, Illinois 61801, U.S.A. ●

THANKS TO REVIEWERS

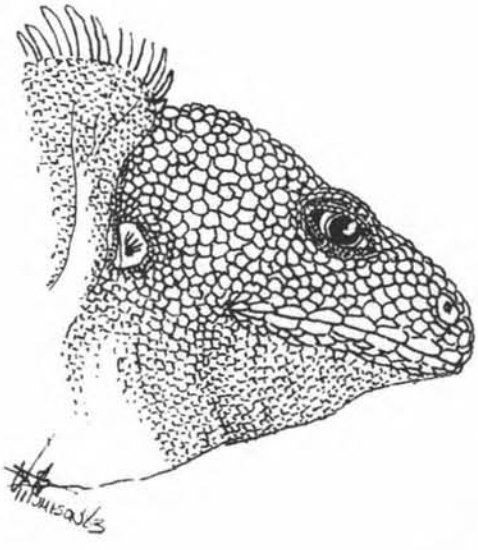
The editor would like to acknowledge the following individuals who reviewed manuscripts for *HR* during the past year. Their service to the Society is greatly appreciated.

Harold Beams
H. Bernard Bechtel
Charles C. Carpenter
Robert Clarke
William E. Duellman
William Dunson
Stanley Dyrkacz
John Ferner
John Frost
Carl Gans
James C. Gillingham
John Groves
Dennis Harris
J. H. Hutchison
John Iverson
John Karges
Timothy Matson
Sam McDowell
Lowell P. Orr
George Pisani
Peter C.H. Pritchard
Eric Rundquist
Michael Ryan
Gordan Schuett
Richard R. Tokarz
Andrew White ●

NEW SECTION EDITOR FOR GEOGRAPHIC DISTRIBUTION

Herpetological Review is pleased to welcome Ellen J. Censky as the new section editor for Geographic Distribution. All manuscripts or other correspondence regarding this section should be sent directly to Ellen at the following address:

Ellen J. Censky
Section of Amphibians and Reptiles
Carnegie Museum of Natural History
4400 Forbes Avenue
Pittsburgh, Pennsylvania 15213, U.S.A.



The present and past editors of *HR* would also like to express their gratitude to Joseph T. Collins, who recently resigned as section editor for Geographic Distribution in order to pursue other interests. J. T. Collins has contributed in so many ways to the Society that it is difficult to adequately thank him. At this time, therefore, we simply offer our sincere thanks for a job well done. ●

HERPETOLOGY POSITION AVAILABLE

A curatorial position is available in the Department of Ichthyology and Herpetology, Royal Ontario Museum, Toronto, Ontario. Appointment will be at senior Assistant Curator or Associate Curator level. Ph.D. graduate in herpetology with field, research, collection, and communications skills and experience. This is a tenure stream, permanent position.

Starting date - July 1, 1984. Closing date for receipt of applications and all documents - March 15, 1984.

For further details, write Dr. E. J. Crossman, Chairman, Search Committee, Dept. of Ichthyology and Herpetology, Royal Ontario Museum, 100 Queen's Park, Toronto, Ontario, Canada, M5S 2C6. ●

26th ANNUAL MEETING OF SSAR HELD AT THE UNIVERSITY OF UTAH

The 1983 Annual Meeting of the Society for the Study of Amphibians and Reptiles was held jointly with the Herpetologists' League in Salt Lake City, Utah, during 7-12 August on the campus of the University of Utah. Local Committee Chairman John M. Legler provided excellent facilities for the nearly 400 members and guests attending from 11 countries. All meeting and exhibit rooms were located in the University Union Building and most attendees were housed in nearby campus dormitories.

SSAR Board of Directors Meeting

The annual meeting of the Board was held on Sunday, 6 August, under the chairmanship of Ralph Axtell. All Board members, except Thomas H. Fritts, were present plus other officers, editors, committee chairs, and a number of visitors. The Board met for over 10 hours and discussed annual reports submitted by each Society officer, editor, committee, and coordinator plus a number of other items. The complexity of the Society continues to increase. SSAR now issues seven publication series, has 11 standing committees, and several coordinators and representatives. In addition to the decisions announced at the business meeting on 9 August (see below), the Board acted upon the following: (1) an additional category, Field Travel for Research, was added to the Grants-in-Herpetology program; (2) a proposal to hold the 1985 meeting at San Diego State University is still under consideration; (3) two symposia, "Predator-Prey Relationships in Lower Vertebrates: Ecology, Behavior, Morphology, and Physiology" and "The Biology of Whiptail Lizards," were approved for the 1984 meeting in Norman; (4) "Larval Amphibia, a Tutorial Workshop" received approval to be held at Norman; and (5) SSAR will sponsor presentation of David Dennis' (new and expanded) slide show "Herpetologists Past and Present" during the 1984 meeting.

Opening Ceremonies

The meeting began officially at 0900 hr on 8 August. On behalf of SSAR and HL, John Legler welcomed members of both organizations and introduced Cedric R. Davern, University of Utah Academic Vice President, who conveyed greetings from the University and wishes for a successful meeting. Robert F. Inger, President of Herpetologists' League, introduced the League's Distinguished Speaker, Roger Conant, who presented a special lecture entitled: "Some Comments and Conclusions on the Genus *Agkistrodon* and its Allies (A summary of the joint work done by Roger Conant and the late H. K. Gloyd)."

Featured Symposium and Regional Herpetological Societies Conference

This year's featured symposium, "Biogeography of the Herpetofauna of Mexico: Perspectives and Approaches," was organized by Larry David Wilson in honor of Hobart and Rozella Smith. The two day program consisted of 22 papers presented by experts from Mexico and the USA.

The 7th Regional Herpetological Societies Conference addressing "Education and Conservation Projects of Regional Herpetological Societies" was sponsored by the SSAR Regional Herpetological Society Liaison Committee. The program, consisting of seven semi-popular lectures, was organized and chaired by Janice J. Perry.

Special Activities, Exhibits, Social Events, and Tours

The Local Committee arranged a number

of special activities including tours of the Brigham Young University Museum in Provo, Veteran's Administration Hospital Venom Laboratory, and Hogle Zoo in Salt Lake City. A number of family tours were also conducted, including trips to the Mormon Temple and Tabernacle, Trolley Square (a shopping center in the old Salt Lake City Trolley barn), Kennecott Copper Mine, and Park City (an old mining town that is now a ski resort).

A display of live amphibians and reptiles occurring in Utah was available for viewing and photography. Several commercial exhibitors and publishers had their products available for inspection. A "Video Techniques Workshop" was organized by John Legler and Helen Lacy at the University's videotape studio. The studio's staff and Legler demonstrated techniques for the use of videotape presentations for teaching and research.

Several excellent social events were held during the week-long meeting. The regional herpetological societies held a well-attended social on Sunday. One of the most popular events of our annual meeting, the traditional social and auction, occurred on Monday with Joseph T. Collins continuing as auctioneer. The sale of herpetologically related art, publications, and other items helped to support local meeting expenses. A Tuesday afternoon picnic was held at the Fort Douglas Military Reservation adjacent to campus. An authentic Mexican meal and strolling Mariachis contributed to an extremely enjoyable evening. An excellent barbecue dinner was held Wednesday night at Snowbird Ski Resort, located in the Wasatch Mountains at an elevation of 2469 meters (8100 ft).

Business Meeting

The annual business meeting of SSAR was called to order by President Ralph Axtell at 1655 hr on 9 August. President Axtell welcomed SSAR members and visitors.

Secretary James Jacob announced that (1) SSAR's newest publication series, *Recent Herpetological Literature*, would now be managed and edited by George Pisani at The University of Kansas; (2) members who are currently scanning journals for titles to be submitted to the *Recent Literature* series should now send all information to Pisani; (3) a list of journals being scanned will appear soon in *Herpetological Review;* (4) members having access to journals which are not being scanned currently were encouraged to contribute titles; (5) air-mail shipment of society publications to non-U.S. members will soon be available for an additional fee; (6) a constitutional amendment will appear on this year's ballot which, if approved, will make the SSAR Publications Secretary an appointed member of the Board of Directors (see *Herpetological Review* 14:4 for details of amendment); (7) George Pisani will be presented with a bound collection of letters from Society members expressing their gratitude for his years of devoted service to the Society; and (8) members who would like to serve on Society committees or host annual meetings were encouraged to contact Jacob, Ralph Axtell, or Carl Gans.

Treasurer Henri Seibert announced that (1) membership for 1982 showed a net increase of 4.3%; (2) the Society's financial status is much improved over the past few years but there will, however, be an increase in dues and subscriptions for 1984 with regular memberships being $22, students $17, and institutional subscriptions $40; and (3) the Board of Directors approved a 1984 budget of $86,055.

Journal of Herpetology Editor Rodolfo Ruibal reported that (1) the time between receipt and final acceptance of manuscripts submitted to the *Journal* is 5-6 months; (2) approximately 50% of the manuscripts submitted are rejected; (3) James L. Vial will assume the duties of Managing Editor for the *Journal* beginning with Volume 18; and (4) the Society is indebted to the members of the Editorial Board and to Stanley Salthe for his service as Managing Editor over the past few years.

Herpetological Review Editor Martin J. Rosenberg announced that (1) the backlog of accepted manuscripts has been reduced; (2) articles are now appearing in 6-10 months; and (3) members with news items or meeting announcements should contact the Editor.

Herpetological Circulars Editor Neil Ford announced that the silver anniversary year membership list (current to 31 December 1982), a brief history of the Society, and a list of herpetological societies (regional, national, and international) has been published as Circular No. 13 and is being sold for $4. Copies are available from the Publications Secretary, Douglas Taylor.

Linda Maxson, Chair of the Grants-in-Herpetology Committee, announced the names of the winners in each category for 1983 and the titles of their proposals (see *HR* 14(3)).

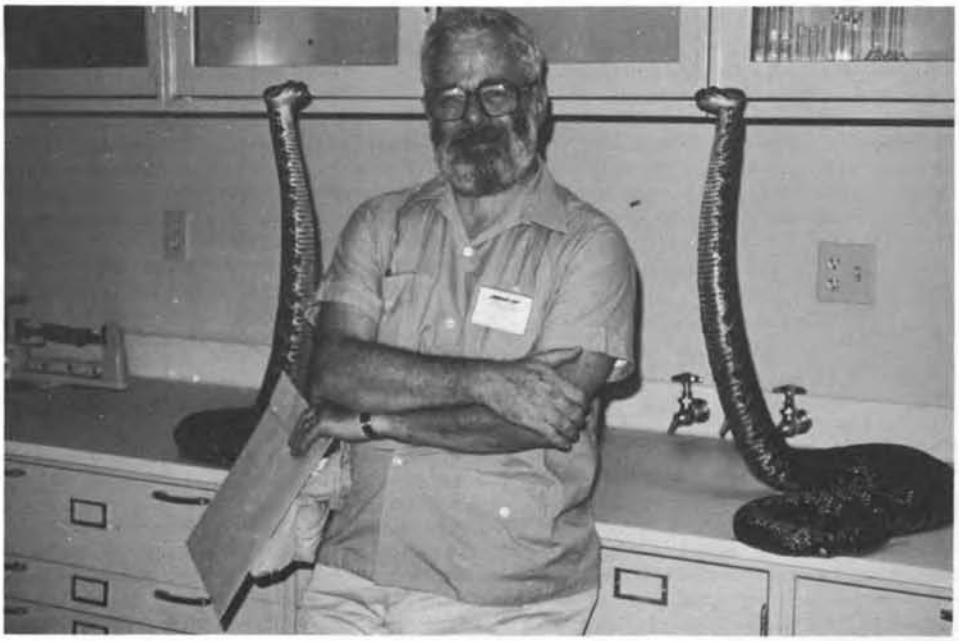
President Axtell announced that Charles R. Crumley was the winner of the 1983 Kennedy Award for the best student paper published in the *Journal of Herpetology* in 1982, for his paper entitled "A cladistic analysis of *Geochelone* using cranial osteology."

Victor Hutchison, Chairman of the Local Committee for the 1984 meeting at the University of Oklahoma, provided an excellent preview of facilities available and activities planned for the Norman meeting. Contact Hutchison for details.

The report of the Nominating Committee was presented by James Vial, Committee Chair. The nominees for SSAR office in 1984 are:

President-elect:
George Pisani and Herbert Dessauer

Secretary:
James Jacob (unopposed)



Treasurer:
Henri Seibert (unopposed)

Board of Directors:
Alan Savitzky, Samuel Sweet,
Timothy Halliday and Ricardo Martori

No additional nominations were received from the floor. James Dixon moved to close nominations (Joseph Collins seconded) and the motion passed with a voice vote. The ballot for 1984 appeared in the September issue of *Herpetological Review*.

There being no new business, President Axtell yielded the floor to Daniel Wilhoft, Chairman of the joint SSAR/HL Resolutions Committee, who presented the following resolutions:

1. *Whereas,* we owe the Local Committee Chairman a great debt of gratitude for his work and dedication which has provided us with an extraordinarily well organized, informative and very enjoyable meeting,
Be It Resolved, that we extend our thanks to the Local Committee Chairman, John M. Legler, whose personal involvement in all aspects of the organization of the meeting resulted in a high level of success and achievement.

President-elect Gans accepting advice on various herpetological matters from his colleagues. (Photo taken at the Veteran's Administration Hospital Venom Laboratory, Salt Lake City.)

2. *Whereas*, we are greatly indebted to the Local Committee for its helpful and efficient contribution to a very successful meeting,
Be It Resolved, that we extend our gratitude to Barbara Bannon, Dan Beck: Hogle Zoo; Jeff Bennion, Sharon Brady: Dancing; Dennis M. Bramble, Michael R. Bruno, Chris Carson: Graphics; Alice Chamberlin, Gloria Cuellar: Socials and Tours; Orlando Cuellar: Socials; Sharon Emerson, Heidi Fain, LaMar Farnsworth: Hogle Zoo; Robert Flint, Mary Fowler, James L. Glenn: Live Exhibit; Katrina Heiner: Secretary; Harold F. Hirth: Poster Session Setup; Jim Hodges, Dave Jensen, Robert Larson: Hogle Zoo; Austin Legler, Avis Legler: Tours; Ed Legler, Gretchen T. Legler, Michele Lemieux: Curatorial; Kerry Matz: Graphics; Jim Mayfield, Chris Moellentine, Mark T. Nielsen, Joyce Nikolai, Louis Porras, Tom Randaggo: Hogle Zoo; J.W. Sites, Jr.: BYU Museum; Taki Skedros, John Skedros: Socials; Anne Spikes: Tours; Maurine Vaughan: Typing; Tim Wahlberg, Dan Wahlberg, Dean Walker, Richard B. Young: Audio Visual.

3. *Whereas*, the Symposium: Biogeography of the Herpetofauna of Mexico: Perspectives and Approaches has contributed to our enthusiasm and knowledge of the sub-tropical herpetofauna,
Be It Resolved, that we express our appreciation to Larry Wilson for bringing together such a distinguished group of contributors.

4. *Whereas*, the meetings were honored by the attendance of Hobart and Rozella Smith,
Be It Resolved, we express our sincere gratitude to both of them for their contribution to our knowledge of Mexican herpetofauna.

5. *Whereas*, the Symposium: Education and Conservation Projects of Regional Herpetological Societies has provided timely and encouraging information relative to herpetological conservation,
Be It Resolved, that we thank Janice Perry for organizing the symposium and the participants for their contributions.

6. *Whereas*, we were the beneficiaries of a fascinating and provocative discussion of the Genus *Agkistrodon*, and its allies,
Be It Resolved, that we express our profound gratitude to Roger Conant not only for his distinguished lecture but also for reminding us of the significant contributions of the late Howard K. Gloyd.

7. *Whereas*, recent heavy rains and flooding in the Salt Lake City area raised fears that the upcoming SSAR/HL meetings might be washed away, and *whereas* our local chairman, John M. Legler, used a little-known and bizarre Australian Aboriginal chant to stop said rains just in time,
Be It Resolved, that John Legler be designated as the official "rain-preventor" for all future meetings, and that said chant be performed in public prior to all social events.

8. *Whereas*, this meeting has been characterized by an astounding abundance of T-shirts, visors, and signs using an excellent logo of a *Chelid* turtle,
Be It Resolved, that John Legler be commended for removing *Chelid* turtles from their previously obscure position in herpetology so that they may now be acknowledged as familiar and fascinating animals.

9. *Whereas*, the Society officers who retired last year have proven their devotion to the Society by promoting its aims,
Be It Resolved, that we thank: Kraig Adler for serving as President; Jim Murphy for serving as Immediate Past President; Jim Bacon and Bob Thomas for their service as Directors.

Papers and Posters Presented:

One hundred and seventy-five papers were presented during the five-day meeting in three consecutive sessions. Titles are presented below in order of session. Extra copies of the Program Booklet, which includes abstracts for most of the papers, are available from Dr. John M. Legler (see announcement below).

AVAILABLE WHILE THEY LAST: ABSTRACTS AND VISORS FROM 1983 SSAR MEETING

There exists a small supply of bound meeting books for the 1983 SSAR/HL Meeting at the University of Utah (containing 182 abstracts). Also there are a few official sun visors left. Both items bear the chelid turtle logo of the meeting. While they last, these items are available at the following prices (near cost):

Meeting Book	$4.40
Visor	$4.60

[Price is postpaid within U.S.A. - Canada. Foreign postage should be figured and paid for individually. Make checks payable to "HL/SSAR".] Mail to:

John M. Legler
Department of Biology
The University of Utah
Salt Lake City, Utah 84112, U.S.A.

POSTER SESSION

BAST, R. E. and R. A. Gibson, *Cleveland State University*
Characterization of the Vitellogenin from the Common Garter Snake *(Thamnophis sirtalis)*.
COOPER, W. E. and L. J. Vitt, *Auburn University; University of California at Los Angeles*
Conspecific Odor Detection in the Broad-Headed Skink *(Eumeces laticeps)*.
HARDY, D. L., *University of Arizona*
Envenomation by *Crotalus scutulatus scutulatus* in Arizona.
JOHNSON, L. F. and J. S. Jacob, *Memphis State University*
Pituitary Activity and Reproductive Cycle of Male *Cnemidophorus sexlineatus*, Six-Lined Racerunner, in West Tennessee.
JOHNSTON, G. F., *Southern Illinois University*
Morphology of the Labial Teeth of Anuran Tadpoles.
KWIAT, G. A. and D. H. Gist, *University of Cincinnati*
Annual Reproductive Cycle of an Ohio Population of the European Wall Lizard, *Podarcis muralis*.
LEGLER, J. M., *University of Utah*
The Chelid Turtles of Australia.
LIEB, C. S., *University of Texas, El Paso*
The *Anolis* Fauna of Mexico: A Preliminary Arrangement of Species Groups.
MACEY, R., *University of California, Santa Cruz*
The Effects of Ecology and Geography on a Hybrid Zone Between Two Subspecies of *Ensatina eschscholtzi*.
MAGNUSSON, W. E., A. P. Lima and M. C. Carvalho, Jr., *Instituto Nacional de Pesquisas da Amazonia, Manaus*
Seed Dispersal by Teiid Lizards in Amazonia.
MIHELY, P. A., *Ohio University*
Comparative Appendicular Anatomy of the Lizard Families Agamidae and Iguanidae.
SEIDEL, M. and S. Inchaustegui, *Marshall University*
Morphological Variation in Hispaniolan *Pseudemys*.
WRIGHT, J. W. and J. O. Hernandes N., *Los Angeles Natural History Museum; UNICOMA, Mexico, D. F.*
Los Cerones: Erpetologos Naturales de Mexico.
ZUG, G. R., A. S. Rand, A. H. Winn, and B. Bock, *National Museum of Natural History; Smithsonian Tropical Research Institute*
Skeletochronology of Panamanian *Iguana iguana*: A Test of Annual Periosteal Growth.

CONTRIBUTED PAPER SESSIONS

Session 1, Chairperson: J. E. Juterbock

TORDOFF, W. III, *California State College, Stanislaus*
Habitat Requirements of the Limestone Salamander, *Hydromantes brunus* (Caudata, Plethodontidae).
HERRINGTON, R. E. and J. H. Larsen, Jr., *Washington State University, Pullman*
Habitat Selection and Utilization by the Larch Mountain Salamander, *Plethodon larselli*.
JONES, L. L. C., *U.S. Fish and Wildlife Service*
Utilization of Rocky Habitat by Salamanders in Northwestern California.
JONES, T. R. and J. P. Collins, *Arizona State University*
The Status of the Salamander, *Ambystoma tigrinum stebbinsi* Lowe, in Southeastern Arizona.
BENESKI, J. T. JR., E. J. Zalisko and J. H. Larsen, Jr., *Washington State University, Pullman*
Demographics of a Long-toed Salamander *(Ambystoma macrodactylum columbianum)* Population During the Spring Breeding Migration.

Session 2, Chairperson: Bruce R. Bury

BERRY, K. H. and A. P. Woodman, *Bureau of Land Management, Riverside, California*
Shell Wear in Desert Tortoises *(Gopherus agassizii)*: Its Use in Determining Adult Age Groups and Analyzing Population Data.
TURNER, F. B., P. A. Medica, and C. L. Lyons, *University of California, Los Angeles; REECO, Las Vegas, Nevada*
Reproduction and Survival of the Desert Tortoise in Ivanpah Valley, California.
CONGDON, J. D., D. W. Tinkle, G. L. Breitenbach and R. C. VanLobenSels, *Savannah River Ecology Lab and University of Michigan*

Nesting Ecology and Nest Predation in *Chelydra serpentina.*
CONGDON, J. D., D. W. Tinkle, G. L. Breitenbach and R. C. VanLobenSels, *Savannah River Ecology Lab and University of Michigan*
Nesting Ecology and Nest Predation in *Chrysemys picta.*
CONGDON, J. D., D. W. Tinkle, G. L. Breitenbach and R. C. VanLobenSels, *Savannah River Ecology Lab and University of Michigan*
Nesting Ecology and Hatching Success in the Turtle, *Emydoidea blandingi.*

Session 3, Chairperson: Walter Tordoff III

JUTERBOCK, J. E., *The Ohio State University, Lima*
Dusky Salamanders as Boy Scouts: Are Males 'Always Prepared' for Reproduction?
SEMLITSCH, R. D. and J. H. K. Pechmann, *Savannah River Ecology Laboratory*
Diel Cycle of Migratory Activity for Several Species of Pond-Breeding Salamanders.
LAYNE, J. R., Jr., *Miami University, Oxford, Ohio*
Diel variation in Critical Thermal Maxima and Minima in Salamanders.
LANNOO, M. J., K. Hoff and R. J. Wassersug, *Department of Anatomy, Dalhousie University, Halifax, N. S.*
Kinematics of Pelagic Prey Capture by *Ambystoma* Larvae.
BEMIS, W. E. and D. Darda, *University of Chicago; University of California, Berkeley*
Development and Evolution of the Salamandrid Frontosquamosal Arch.

Session 4, Chairperson: James L. Christiansen

CONGDON, J. D. and J. W. Gibbons, *Savannah River Ecology Laboratory*
Relationships of Reproductive Characteristics to Body Size in *Pseudemys scripta.*
MORREALE, S. J., J. D. Congdon, and J. W. Gibbons, *Savannah River Ecology Laboratory*
Movements and Activity Levels of the Slider Turtle *(Pseudemys scripta)* with Relation to Reproductive Strategies.
WILHOFT, D. C. and E. C. Hotaling, *Rutgers University, Newark, New Jersey*
Egg Position and Weight of Hatchling Snapping Turtles *(Chelydra serpentina)* in Natural Nests.
CRASTZ, F., *Universidad de Panama*
Mechanism of "Arribadas".
RAYMOND, P. W. and L. M. Ehrhart, *University of Central Florida, Orlando*
The Effects of Beach Restoration on Loggerhead Turtle *(Caretta caretta)* Nesting in South Brevard County, Florida.
EWERT, M. A., *Indiana University, Bloomington*
Embryonic Aestivation in Turtle Eggs.

Session 5, Chairperson: Rodolpho Ruibal

WILLIAMS, T. A. and J. H. Larsen, *North Central College, Naperville, Illinois; Washington State University, Pullman*
Caudal Morphology of the Genus *Ambystoma.*
SESSIONS, S. K. and J. Kezer, *University of California, Berkeley; University of Oregon*
Evolution of the Plethodontid Genus *Aneides:* A Cytological Perspective.
SEVER, D. M. and L. D. Houck, *St. Mary's College, Notre Dame, Indiana; University of Chicago*
Preliminary Observations on Spermatophore Formation and Decapping in *Desmognathus ochrophaeus.*
ANDERSON, K., *New York University, New York, New York*
Nucleolar-Organizer Regions in Holarctic *Hyla* Chromosomes.
BUSACK, S. D., *University of California, Berkeley*
Biochemical Divergence in a Mediterranean Herpetofauna: Preliminary Results in a Test of Vicariance Biogeography.
JOGLAR, R., *University of Kansas, Lawrence*
Phenetic Analysis of the *Eleutherodactylus* (Anura: Leptodactylidae) of Puerto Rico.

Session 6, Chairperson: Justin Congdon

IVERSON, J. B., *Earlham College, Richmond, Indiana*
Preliminary Studies of the Population Dynamics of *Kinosternon flavescens* in the Nebraska Sandhills.
MACCULLOCH, R. D. and D. M. Secoy, *Royal Ontario Museum; University of Regina*
Demography, Growth and Food of *Chrysemys picta bellii* in Saskatchewan.
KOZUBOWSKI, M. M. and A. W. Smits, *University of Kansas, Lawrence*
Hemodynamic Responses to Graded Hemorrhage in *Chrysemys scripta.*
SMITS, A. W. and M. M. Kozubowski, *University of Kansas, Lawrence*
Blood Volume Regulation and Body Fluid Compartmentation in *Chrysemys scripta.*
LONG, D. R., *Texas Tech University, Lubbock*
Lipid Utilization in the Reproductive Effort of Female *Kinosternon flavescens.*
LAMB, T. and J. Congdon, *Savannah River Ecology Laboratory*
Ash Content: Comparisons Between Turtle Eggshell Types.

Session 7, Chairperson: Robert M. Winokur

ZUG, G. R., H. A. Wynn and C. Ruckdeschel, *National Museum of Natural History; Cumberland Island, Georgia*
Age Determination of *Caretta caretta* by Incremental Periosteal Growth.
NIELSEN, M. T., *University of Utah*
Cloacal Bursae in Recent Turtles: The Mucosal Lining.
BRUNO, M. R., *University of Utah*
Nictitating Membranes and Associated Ocular Glands in Recent Turtles.
BRAMBLE, D. M., J. H. Hutchison, and J. M. Legler, *University of Utah; University of California, Berkeley*
Kinosternid Shell Kinesis.

Session 8, Chairperson: Kraig Adler

CORN, P. S., *Colorado State University*
Size, Color and Mating Success of Male Chorus Frogs, *Pseudacris triseriata.*
FORESTER, D. C., *Towson State University, Towson Maryland*
Sexual Selection in the Spring Peeper: Bigger is Not Necessarily Best.
SULLIVAN, B. K., *Arizona State University, Tempe*
Female Choice in Woodhouse's Toad *(Bufo woodhousei australis).*
WOOLBRIGHT, L. L., *State University of New York, Albany*
Sexual Dimorphism in *Eleutherodactylus coqui* (Anura: Leptodactylidae).

Session 9, Chairperson: James F. Berry

HUTCHISON, J. H., *University of California, Berkeley*
Two New and Unusual Genera of Paleocene Emydidae from Wyoming.
ROSE, F. L. and J. L. Dobie, *Texas Tech University; Auburn University*
***Chrysemys-Pseudemys-Trachemys:* A Taxonomic Dilemna.**
LOVICH, J. E., C. H. Ernst, and S. W. Gotte, *George Mason University, Fairfax, Virginia*
Geographic Variation in *Chinemys reevesii* and the Status of *Geoclemys grangeri* (Schmidt).
CHRISTIANSEN, J. L., *Drake University*
Raccoon Removal and Turtle Nesting Success in Eastern Iowa.

Session 10, Chairperson: Ronald W. Heyer

PERRILL, S. A., *Butler University*
Male Mating Behavior in *Hyla regilla.*
ZWEIFEL, R. G., *American Museum of Natural History*
Call Differentiation in Australian Microhylid Frogs.
SCOTT, N. J., Jr., A. L. Aquino, D. Norman and L. West, *University of New Mexico, Servicio Forestal, Paraguay; U. S. Peace Corps, Paraguay*
It's A Frog Eat Frog World: Food Habits of the Anurans of the Paraguayan Chaco.
SWEET, S. S., *University of California, Santa Barbara*
Mechanics of a Natural Extinction Event: *Rana boylii* in Southern California.

Session 11, Chairperson: Orlando Cuellar

ANDERSON, R. A., *University of California, Los Angeles*
Ecology of Foraging of *Cnemidophorus tigris.*
JONES, T. R., *Arizona State University*
Factors Affecting Home Range Size in the Iguanid Lizard *Sceloporus undulatus.*
van BERKUM, F. H., *University of Washington, Seattle*
Thermal Sensitivity of Sprint Speed in Anoline Lizards.
CARPENTER, G. C., *University of Wyoming*
Chemical Communication in the Western Banded Gecko *(Coleonyx variegatus).*
CROWLEY, S. R., *University of New Mexico, Albuquerque*
Aggressiveness and Vocalization in the Leopard Lizard *(Gambelia wislizenii):* the Influence of Temperature.
SELCER, K. W., *Texas Tech University, Lubbock*
Reproduction and Associated Lipid Utilization of the Introduced Mediterranean Gecko, *Hemidactylus turcicus.*

Session 12, Chairperson: Rick Shine

TORDOFF, W. III, *California State College, Stanislaus*
Population Biology of the Limestone Salamander, *Hydromantes brunus* (Caudata, Plethodontidae).
ROBERTS, J. D., *University of Western Australia*
Calling Tactics in the Frog *Heleioporus eyrei* (Myobatrachidae).
HEYER, W. R., *Smithsonian Institution*
Zoogeography of the *Eleutherodactylus guentheri* cluster (Anura: Leptodactylidae) in the Atlantic Forests of South America.

CHANNING, A. and W. McAllister, *University of the Western Cape, South Africa; University of Guelph, Canada*
Pattern Polymorphism in *Hyperolius marmoratus* (Anura: Hyperoliidae).
DUTTA, S. K., *University of Kansas*
Distribution and Morphological Variation in the *Rana limnocharis* Complex in Asia.
LEWIS, D. L., G. T. Baxter, K. M. Johnson and M. D. Stone, *University of Wyoming*
A Status Report on the Wyoming Toad *Bufo hemiophrys baxteri.*

Session 13, Chairperson: George R. Zug

CAROTHERS, J. H., *University of California, Berkeley*
Sexual Dimorphism and Sexual Selection in Some Herbivorous Lizards.
CHENG, H. Y., *Tulane University, New Orleans*
Predation, Tail Regeneration and Reproduction in Two Sympatric Geckos *(Sphaerodactylus)* in Hispaniola.
LEVINSON, L., *Nassau Community College, Garden City, New York*
A Comparison of Anoline Toepad Ultrastructure.
LUKE, C. A., *University of California, Berkeley*
Convergent Evolution of Lizard Toe Fringes.
BAUER, A. M., *University of California, Berkeley*
Allometry in Scansor Number and Surface Area in Lizards of the Genus *Gekko*.

Session 14, Chairperson: William S. Brown

BURY, R. B. and P. S. Corn, *U. S. Fish and Wildlife Service*
Morphological Variation in Racers, *Coluber constrictor*, from Colorado and Utah.
SHINE, R., *University of Sydney*
Ecology of Australian File-Snakes *(Serpentes: Acrochordidae).*
DIXON, J. R. and R. H. Dean, *Texas A & M University*
The *Hypsiglena torquata - ochrorhyncha* Controversy Revisited.
AIRD, S. D., *Colorado State University, Fort Collins*
Genetic Variation in Rattlesnake Venom Proteins.
McDONALD, H. S., *Stephen F. Austin State University, Nacogdoches*
Induced Immobility in Racers *(Coluber)* and Similar Diurnal Hunters.

Session 15, Chairperson: Sharon Emerson

BLACK, D. G., *Monash University, Melbourne*
Encephalization of Australian Lizards.
REILLY, S. M., *Southern Illinois University, Carbondale*
Thermal Ecology of the Highland Chameleons of Kenya.
TSUJI, J. S., *University of Washington*
Inverse Acclimation in Temperate and Tropical *Sceloporus* Lizards.

Session 18, Chairperson: Samuel B. McDowell

SAVITZKY, A. H., *Old Dominion University*
Vertebral Protrusion in Snakes: Evidence for a Novel Defensive Mechanism.
SCHUETT, G. W., D. L. Clark and F. Kraus, *Central Michigan University; University of Michigan*
A Moving Tale: Feeding Mimicry in the Rattlesnake *Sistrurus catenatus*.
SOMERS, A. B. and R. W. Van Devender, *A.S.U., Boone, North Carolina*
Relative Palatability of "mimetic" salamanders to garter snakes.
CADLE, J. E., *Smithsonian Institution*
Phylogenetic Relationships of African Back-Stabbing Snakes, Genus *Atractaspis.*

Session 15, Chairperson: Alan E. Leviton

BROWN, C. W., *George Mason University*
A Study of Variation in Eastern Timber Rattlesnakes, *Crotalus horridus*.
MACKESSY, S., *University of California, Santa Barbara*
Changes in Rattlesnake Venom Composition: Ontogenetic Aspects.
OTTLEY, J. R. and R. W. Murphy, *Brigham Young University; University of California, Los Angeles*
Rattle-Loss in Insular Rattlesnakes: A Question of Natural Selection or Chance?
GRAVES, B. M., and D. Duvall, *University of Wyoming*
The Role of Skin Lipids in Den Location by Neonatal Prairie Rattlesnakes and Mouth-gaping in Non-feeding Context.
de QUEIROZ, A., *Oakland, California*
Effects of Prey Type on the Prey-Handling Behavior of the Bullsnake, *Pituophis melanoleucus*.

Session 16, Chairperson: Marvalee H. Wake

MOK, W. Y. and C. M. Carvalho, *Instituto Nacional de Pasquisas da Amazonia, Manaus, Brazil*
Occurrence of *Mycobacterium chelonei* in *Bufo marinus* and *Bufo granulosus*.
GREEN, D. M., *University of California, Berkeley*
Chromosome Number Reduction and Homosequentiality in the 24-Chromosome Frog *Rana dybowskii* from Korea and Related Species.
ROMANO, M. A., D. B. Ralin and C. W. Kilpatrick, *Miami University, Oxford, Ohio*
The Tetraploid Treefrog *Hyla versicolor*: Evidence for a Single Origin from the Diploid *H. chrysoscelis*.
HESS, J. B., *Central Missouri State University, Warrensburg*
Frequency Changes of the Green-Spot Allele in Colorado Chorus Frogs.
MAXSON, L. R. and C. W. Myers, *University of Illinois, Urbana; American Museum of Natural History*
Albumin Evolution in Dendrobatid Frogs: A Preliminary Report.

Session 17, Chairperson: Laurie J. Vitt

VANGILDER, L. D., *Savannah River Ecology Laboratory*
Behavior and Body Temperatures of the American Alligator During Winter.
GUILLETTE, L. J., and S. L. Nazaran, *Wichita State University, Wichita, Kansas*
Uterine Shell Glands and Shell Formation in Several Lizard Species.
MOODY, S. M., *Ohio State University, Athens, Ohio*
Endolymphatic Sacs in Lizards: Phylogenetic and Functional Considerations.
SULLIVAN, R. M., *University of South Alabama, Mobile*
Paleocene Fossil Anguid Lizards and the Phylogeny of the Subfamilies Odaxosaurinae, Glyptosaurinae and Anguinae (Reptilia, Anguidae).

Session 18, Chairperson: Robert F. Inger

DEGANI, G. and E. Nevo, *Migal, Galilee Technological Center, Kiryat Shmona, Israel*
Osmotic of Blood and Plasma in Tadpoles and Juveniles *Pelobates syriacus*.
WYGODA, M. L., *Seton Hill College, Greensburg, Pennsylvania*
Low Evaporative Water Loss is Common in Arboreal Frogs.
EMERSON, S. B., *Field Museum of Natural History*
Skull Shape in Frogs - A Preliminary Survey.
MILLER, K., J. Franzese and W. R. Graf, *Franklin and Marshall College*
The Effect of Body Size on Fast-Start Locomotor Performance by African Clawed Frogs, *Xenopus laevis*.
RUIBAL, R. and V. Shoemaker, *University of California, Riverside*
Dermal Bony Scutes in Anurans - Osteoderms or Scales?

Session 19, Chairperson: Frederick B. Turner

BROOKS, G. R., *College of William and Mary*
Movement of Individuals within Populations of *Anolis lividus*.
CUELLAR, O., *University of Utah*
The Natural Behavior of the Lizard *Cnemidophorus tigris*.
MOEHN, L. D., *Illinois College, Jacksonville, Illinois*
Aggressive Behavior and Assessment Strategy in the Broadhead Skink *Eumeces laticeps*.
STEWART, J. R., *University of Tulsa*
Female Temperature Preference: An Ecological Advantage to Egg Retention in Viviparous Lizard.
HUEY, R. B. and P. E. Hertz., *University of Washington; Barnard College*
Is a "Jack-of-All-Temperatures" a "Master of None"?

Session 20, Chairperson: James L. Vial

PLUMMER, M. V., *Harding University*
Growth and Maturity in Green Snakes *(Opheodrys aestivus)*.
DUVALL, D. and M. B. King, *University of Wyoming*
Migration and Predatory Ecology of *Crotalus viridis viridis*.
GREGORY, P. T., *University of Victoria, Victoria, B.C.*
Phenology of Communally Denning Garter Snakes *(Thamnophis)* in Central British Columbia.
BREITHAUPT, B. H. and D. Duvall, *University of Wyoming*
The Oldest Record of Ophidian Aggregation.
DETTERLINE, J. L., J. S. Jacob and W. E. Wilhelm, *Memphis State University*
A Comparison of the Endoparasites of the Cottonmouth *(Agkistrodon piscivorus)* with Three Sympatric Species of Watersnakes *(Nerodia)* from Alabama.

Session 21, Chairperson: Joseph A. Tihen

VIAL, J. L. and J. R. Stewart, *University of Tulsa*
Acyclic Reproduction in a Viviparous Anguid Lizard.
McDOWELL, S. B., *Rutgers University, Newark*

The Cervicomandibularis Muscle of Colubroid Snakes.
VITT, L. J. and W. E. Cooper, *University of California, Los Angeles; Auburn University*
Sexual Dimorphism in the Broad-Headed Skink: Indirect Evidence for Sexual Selection.
HARRIS, D. M., *University of Michigan*
A Re-Evaluation: Do the Macroteiid and Microteiid Lizards Comprise a Monophyletic Group?

Session 22, Chairperson: Sherman A. Minton, Jr.

REYNOSO, M. F., *Universidad Autónoma de Baja California Sur*
The Herpetofauna of Isla Espiritu Santo, Baja California Sur, Mexico.
VOGT, R. C., *Universidad Nacional Autonoma de Mexico*
Community Analysis of a Tropical Herpetofauna in Veracruz, Mexico.
INGER, R. F. and H. B. Shaffer, *Field Museum of Natural History*
Faunal Sampling in the Western Ghats.
SUBBA RAO, M. V., K. Rao, K. and S. Eswar, *Andhra University, Visakhapatnam, India*
Some Rare and Common Herpetiles of Andhra Pradesh.

Session 23, Chairperson: James R. Dixon

ALDRIDGE, R. D., *St. Louis University*
Relationship Between Snout-Vent Length, Clutch Size and Number of Atretic Follicles in Snakes.
FORD, N. B., *University of Texas at Tyler*
Reproductive Characteristics of Five Species of Garter Snakes, *Thamnophis*.
GIBSON, A. R., R. E. Bast and P. Bryan, *Cleveland State University*
Noninvasive Monitoring of Female Reproduction in the Common Garter Snake *(Thamnophis sirtalis)*.
MINESKY, J. J. and R. D. Aldridge, *St. Louis University*
Frequency of Reproduction in the Queen Snake *(Regina septemvittata)*.
SEIGEL, R. A. and H. S. Fitch, *University of Kansas*
Variation in Clutch Size in Four Species of Snakes in a Fluctuating Environment.

Session 24, Chairperson: John W. Wright

PAPENFUSS, T. J., *University of California, Berkeley*
Opportunities for Research in Amazonian Peru.
JENSSEN, T. A. and D. L. Marcellini, *Virginia Tech, Blacksburg, Virginia; National Zoological Park*
Competitive Interference between the Puerto Rican Lizards *Anolis cooki* and *Anolis cristatellus* (Squamata: Iguanidae).
RAY, D. and A. Ch. Rai, *University of North Bengal, Darjeeling*
Annual Testicular Cycle of Indian Salamander *Tylototriton verrucosus* Anderson (Urodela: Amphibia).

Session 25, Chairperson: Dennis M. Bramble

BERRY, K. H. and A. P. Woodman, *Bureau of Land Management, Riverside, California*
A Comparison of Death Rates in 14 Desert Tortoise *(Gopherus agassizii)* Populations in California.
TAYLOR, H. L., *Regis College, Denver*
Zones of Intergradation Involving the Teiid Lizard, *Cnemidophorus tigris*, in Southwestern Utah and Northwestern Arizona.
LEVITON, A. E. and M. L. Aldrich, *California Academy of Sciences; AAAS*
John Anderson (1883-1900): Victorian-Era Herpetologist.
WALKER, J. M., *University of Arkansas*
Comparison of Reproductive Characteristics in Parthenogenetic and Gonochoristic Populations of *Cnemidophorus lemniscatus* in Suriname.
GRAHAM, T. E., *Worcester State College, Worcester, Massachusetts*
Status of the Endangered Red-Bellied Turtle, *Pseudemys rubriventris*, in Southeastern Massachusetts.
LEGLER, J. M. and R. M. Winokur, *University of Utah and University of Nevada, Las Vegas*
Vascular Papillae in the Buccopharyngeal Mucosa of *Carettochelys insculpta* (Cryptodira; Carettochelyidae).

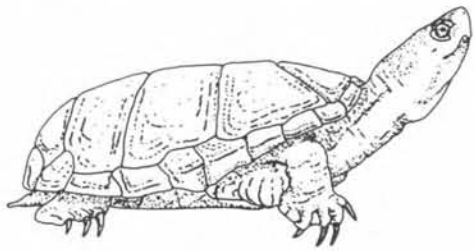
FEATURED SYMPOSIUM

Biogeography of the Herpetofauna of Mexico: Perspectives and Approaches.

A Symposium in Honor of Hobart M. Smith and Rozella B. Smith

Organized by Larry David Wilson

Session 1, Chairperson: Larry D. Wilson



WILSON, L. D., *Miami-Dade Community College*
Introduction and Dedication.
DUELLMAN, W. E., *University of Kansas*
The Herpetology of Mexico: The Hobart M. Smith Era.
SMITH, H. M. and R. B. Smith, *University of Colorado, Boulder*
National Responsibility for Maturation of Mexican Herpetology.
KEZER, J., *University of Oregon*
Carlos and Miguel Ceron of Cuautlapan, Mexico: Their Contributions to the Mexican Collections of Hobart Smith and Edward Taylor.

Session 2, Chairperson: Wilmer W. Tanner

FLORES-VILLELA, O. A., *Universidad Nacional Autónoma de Mexico*
The History of Mexican Herpetology.
CASAS-ANDREU, G., *Universidad Nacional Autónoma de Mexico*
The Current Status of Herpetological Research by Mexican Scientists.
SAVAGE, J. M., *University of Miami*
Vicariance and Dispersal Events, Refugia and Historical Origins.

Session 3, Chairperson: Wilmer W. Tanner

DIXON, J. R. and F. S. Hendricks, *Texas A & M University*
Distribution of the Herpetofauna of the Lowlands of the Western Gulf Coast of Mexico and Adjacent Texas.
MORAFKA, D. J., G. A. Adest and G. Aguirre L., *California State University; University of California, San Diego; Instituto de Ecologia, Mexico*

Hobart Smith enjoying good food and good conversation at the outdoor meal and social, which featured strolling Mariachis.

Participants in the featured symposium at the 26th Annual Meeting of the SSAR presented in honor of Hobart M. and Rozella B. Smith, titled "Biogeography of the Herpetofauna of Mexico: Perspectives and Approaches."

The Differentiation of North American Deserts: A Biochemical Phylogenetic Evaluation of a Geofloral Model Utilizing Squamate Taxa.

CASAS-ANDREU, G., *Universidad Nacional Autónoma dė Mexico*

Biogeography of the Herpetofauna of the West Mexican Province: A Preliminary Proposal for Subdivision into Biotic Districts.

Session 4, Chairperson: Roger Conant

MURPHY, R. W., *University of California, Los Angeles*

Biogeography of the Baja California Herpetofauna; Re-evaluations and Further Considerations.

LINER, E. A., *Houma, Louisiana*

The Biogeography of the Herpetofauna of the Northern Sierra Madre Oriental of Mexico.

McCRANIE, J. R. and L. D. Wilson, *Miami, Florida; Miami-Dade Community College*

The Biogeography of the Herpetofauna of the Pine-Oak Woodlands of the Sierra Madre Occidental.

BRATTSTROM, B. H., *California State University, Fullerton*

Biogeography of the Revillagigedo Islands, Mexico.

JOHNSON, J. D., *Texas A & M University and El Paso Community College*

A Biogeographic Analysis of the Herpetofauna of the Northwestern Portion of Nuclear Central America.

SÁNCHEZ-HERRERA O., *Universidad Nacional Autónoma dė Mexico*

The Valley of Tehuacan-Cuicatlan as a Biotic Province of Mexico.

Session 5, Chairperson: Richard G. Zweifel

PAPENFUSS, T. J., D. B. Wake and J. F. Lynch, *University of California, Berkeley; Smithsonian Institution, Edgewater, Maryland*

Biogeography of Mexican Lungless Salamanders.

BEZY, R. L., *Natural History Museum of Los Angeles County*

Systematics and Biogeography of the Xantusiid Lizard Genus *Lepidophyma* in Mexico.

GOOD, D. A., and J. W. Wright, *University of California, Berkeley; Natural History Museum of Los Angeles County*

Evolution and Biogeography of Gerrhonotine Anguid Lizards.

WEBB, R. G., *University of Texas, El Paso*

Preliminaries Concerning the Systematics of the *Sceloporus poinsetti* Complex.

BERRY, J. F., *Elmhurst College, Elmhurst, Illinois*

Biogeography of the *Kinosternon scorpioides* Complex (Testudines: Kinosternidae) in Mexico.

WRIGHT, J. W., *Natural History Museum of Los Angeles*

Evolution and Biogeography of the *Cnemidophorus* of Mexico.

REGIONAL HERPETOLOGICAL SOCIETIES SYMPOSIUM

Education and Conservation Projects of Regional Herpetological Societies

Organized and Chaired by Janice Perry

ROMNEY, E. and D. Jensen, *Utah Herpetological Society*

Meeting the Challenges of a Small Herp. Society.

BISHOP, M., *Greater San Antonio Herpetological Society*

Herpetofauna and the Locals.

LAMBERT, M. (presented by K. Adler), *British Herpetological Society*

Current Activities of the British Herpetological Society in Relation to Europe and the Commonwealth.

BLACK, J., *Oklahoma Herpetological Society*

Oklahoma Rattlesnake Roundups.

BADER, R., *Virginia Herpetological Society*

Establishing the Range of the Pine Barrens Tree Frog, *Hyla andersoni* in North Carolina.

De LISLE, H., *Southwestern Herpetologists Society*

Herps, Sex and Bureaucrats: The Problems of Captive Reptile Reproduction for Fish and Game Officials.

COLLINS, J., *Kansas Herpetological Society*

Kansas Herpetological Society - Ten Years of Progress.

SSAR Committees for 1983-1984

Following the Salt Lake City meeting, President Axtell appointed the following committees, coordinators and representatives for the current year, to report to the Board at the Norman meeting in August of 1984. Individuals with important matters pertaining to these activities should contact the relevant committee chair. Addresses for committee chairs are included on the inside rear cover of each issue of *Herpetological Review*.

Grants-in-Herpetology: Linda R. Maxson (Ch), James P. Bacon, Don C. Forester, John B. Iverson, Robert W. Murphy, Malvin L. Skaroff.
Conservation: Patricia Riexinger (Ch), John L. Behler, William S. Brown, Kenneth Dodd, Jr., Renė E. Honegger, Paul E. Moler.
Kennedy Student Award: J. Eric Juterbock (Ch), Robert E. Gatten, Jr., Ken R. Marion, John S. Mecham, Laurie J. Vitt.
Nominating: Diane M. Secoy (Ch), James R. Dixon, Stephen R. Edwards, Ernest A. Liner, Daniel C. Wilhoft.
Regional Society Liaison: Jeffrey H. Black (Ch), Harold DeLisle, James D. Fawcett, Joseph C. Mitchell, John Simmons, Tom Vermersch, George D. Whitney.
Zoo Liaison: Peter J. Tolson (Ch), Jonathon A. Campbell, Mike Goode, John D. Groves, Hugh Quinn, Susan Schafer, R. Wayne VanDevender.
Long-range Planning: James L. Christiansen (Ch), Kraig Adler, Joseph T. Collins, James S. Jacob, Henri C. Seibert.
MEETINGS (SSAR/HL): Lynne Houck (Ch), Ronald A. Brandon, William Cooper, Arthur C. Echternacht, James S. Jacob.
Herpetological Resources (SSAR/HL/ASIH): Roy W. McDiarmid (Ch), Pere Alberch, Alan E. Leviton, Scott Moody, Charles W. Myers, Linda Trueb.
RESOLUTIONS (SSAR/HL): Robert A. Thomas (Ch), Others to be appointed at Norman meeting.
Common and Scientific Names Coordinator: Joseph T. Collins.
Translations Coordinator: Robert D. Aldridge.
Representative to Association of Systematic Collections: Max A. Nickerson.

1984 ANNUAL MEETING

The 1984 annual meeting of SSAR will be held jointly with the American Society of Ichthyologists and Herpetologists (ASIH) and the Herpetologists' League (HL) at the University of Oklahoma, 28 July - 3 August. The call for papers, advanced registration forms, and more detailed information will be mailed to members of the sponsoring societies in early March.

Symposia and Workshops with their organizers are: Predator-Prey Relations in Lower Vertebrates (Martin E. Feder and George Lauder); Biology of *Cnemidophorus* (John W. Wright); Management of Captive Populations of Endangered Amphibians and Reptiles (SSAR, Peter J. Tolson); Tutorial Workshop in Amphibian Larval Biology (Richard Wasserzug).

Introductory Session Presentations will include the ASIH Presidential Address (Marvalee Wake), HL Distinguished Herpetologist Lecture (David Wake), and the ASIH Distinguished Fellow Lecture (John E. Randall, "On the Importance of Marine Sanctuaries to Ichthyological Research").

Accommodations will be in motel-style dormitories; each room has two single beds and each two rooms share a bath. ($9.50 per person, double; $16.00, single; linens furnished.) Cafeteria-style, all-you-can-eat meals will cost $10.75/day. Blocks of rooms at discount rates will be available at local motels (2-3 miles from campus). Campgrounds are available on Lake Thunderhead (Little River State Park) about 12 miles east of Norman. Childcare facilities will be available.

Transportation by air should be arranged to Oklahoma City. Travel from the airport to and from Norman (20 miles) has been contracted with Metro Limousine Service at $6.00 per person each way.

Paper and Poster Sessions. Due to the expected attendance, oral presentation of papers will be limited. Members are urged to give poster presentations. Authors will be scheduled in the program to be present at their posters and discussion. Deadline for the receipt of abstracts will be 25 April 1984 and will be rigidly enforced. Awards for best student papers will be given by ASIH and HL and, for best poster presentation, by HL.

Live Exhibits (SSAR, Oklahoma Herpetological Society). Many of the species of amphibians and reptiles found in Oklahoma will be on display throughout the meeting. Facilities for photography of the animals will be available in the exhibit area.

Art and Photography Exhibit (SSAR). All members of the three societies are urged to bring their own herpetological and ichthyological art work (paintings, drawings, sculptures) and photographs ready for hanging or display in the Stovall Museum gallery.

Commercial Exhibits. Publishers, manufacturers and suppliers of items of interest to the membership are invited to participate as exhibitors. Detailed information and sample contract forms may be obtained from Neil B. Ford, Department of Biology, University of Texas at Tyler, Tyler, TX 75701.

Auction (SSAR). All members are solicited for herpetological and ichthyological books or other appropriate items to be auctioned to raise funds for support of the meeting. All contributors will receive receipts; gifts are tax-deductible. Any funds not needed for support of the annual meeting will be divided among the three sponsoring societies. Send your duplicate books or other items directly to the meeting chairman or bring them to the meeting!

Social Events. There will be a free social for all registrants on Sunday evening, 29 July. The Oklahoma Zoological Society and Oklahoma City Zoo will host an open house and barbecue on the evening of 30 July. On Wednesday, 1 August, there will be a picnic featuring Oklahoma Indian dance ceremonies for entertainment; the picnic will be followed by the auction. On Thursday, 2 August, a roast bison banquet preceded by a social hour and sponsored by ASIH will be held; all registrants are invited to attend. Tours for families and partners of members have been planned to areas of interest (Cowboy Hall of Fame, Indian City, Museum of Plains Indians, etc.).

Additional information may be obtained from Victor H. Hutchison, Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019, U.S.A. Telephone (405)-325-6721. ●

1983 INVENTORY AVAILABLE
&
REQUEST FOR INFORMATION FOR THE 1984 EDITION
INVENTORY OF LIVE REPTILES AND AMPHIBIANS IN CAPTIVITY

The 1983 edition contains an inventory of living specimens held in 198 reptile and amphibian collections (75 public and 123 private) from ten countries. Information is current as of 1 January 1983 with 366 genera, 911 species, and 1,191 forms represented. Information on reproduction includes 367 taxa along with a 40 page bibliography on breeding. Published by the author. 1983. 254 pp., $25.00 ($20.00 paperbound) plus $1.50 postage.

This inventory is an ongoing project with corrections, updates, and expansions being planned over the next several years. All institutions worldwide holding live reptiles and/or amphibians are asked to submit inventories and breeding information current up to January 1st of each year. Private collectors are also welcomed to submit information, but emphasis is on those collections which have breeding potential, have had breeding success in the past, or hold species which are rare or difficult to obtain. I hope to compare annual inventory data, as well as producing the inventory and breeding information.

I am now preparing to receive information current as of 1 January 1984. If you keep live reptiles and/or amphibians in captivity, please respond with the information requested below.

(1) A complete inventory of all reptiles and amphibians held in your collection current as of January 1st. Sexes should be included and can be listed "male/female/unknown sex".

(2) A list of all species which bred and produced young during 1983, including numbers of young for each species.

(3) Any miscellaneous breeding information (use the information presented in the 1983 edition as a guide). Include detailed information for all species which you feel should be listed.

(4) A listing of any publications, including books, museum bulletins, journals, magazines, etc., with reference to reproduction in reptiles and amphibians. References pertaining to the care of individual species as well as more general articles relating to temperature, light cycle, hibernation, etc. are of interest.

Deadline for receipt of information is March 1st.

All orders and information should be sent to:

Seattle, Washington 98103, U.S.A.

IN MEMORIAM

DR. EDWARD ELKAN 1895-1983

Dr. Edward Elkan, who was recognized internationally for his work on the pathology and diseases of reptiles and amphibians, died at the age of 88 on 4th July 1983.

A fund in memory of Dr. Elkan has been established and will be used to perpetuate his name and work. A number of commemorative ventures have been proposed and will be considered in due course. The most pressing requirement, however, is to ensure that Dr. Elkan's unique collection of microscope slides and other pathological specimens is properly collated, mounted and maintained. Much of the material is already housed at the Royal College of Surgeons: Dr. Elkan passed it on to me before he died and was anxious that it should remain intact and serve as a working collection. This will be supplemented with a number of Dr. Elkan's drawings, reprints and reference books. It is our intention that the "Edward Elkan Reference Collection of Lower Vertebrate Pathology" should be widely used for study by herpetologists, pathologists and research workers from a range of disciplines.

All colleagues, friends and admirers of Dr. Elkan are invited to contribute to this Appeal. Cheques should be made payable to "The Edward Elkan Memorial Fund" and forwarded to the address below. Comments or suggestions concerning the Fund will be welcomed and should be submitted in writing. In order to minimise expenditure an acknowledgement will only be sent if specifically requested. However, a full list of subscribers will be compiled and affixed to the Collection. Reports of the Fund's progress will also appear regularly in the herpetological literature.

Return donations, comments, or suggestions to:

MEETINGS

AUSTRALASIAN HERPETOLOGICAL CONFERENCE

The Royal Zoological Society of New South Wales, the Australian Society of Herpetologists and the Australian Museum will sponsor the Australasian Herpetological Conference on 28-31 August 1984 at the Australian Museum, Sydney, Australia. Participation in the conference is welcomed from both professional and amateur herpetologists. Publication of the Proceedings is planned.

The following symposia will be offered at this meeting: Ecological Biogeography of the Australasian Herpetofauna; Physiological Ecology of Aquatic Reptiles; Rare and Endangered Australasian Frogs and Reptiles; Population Ecology of Frogs and Reptiles; Reproduction and Development of Frogs and Reptiles; Phylogeny of Australasian Elapid Snakes; and Chromosomes and Evolution of Australasian Frogs and Reptiles. There will also be a workshop on Husbandry and Captive Breeding, to take place at the Taronga Zoo.

The registration and conference dinner fees for this meeting are approximately $50 and $25, respectively. A formal call for papers will be made in late 1983. For further information, or to be placed on the mailing list, write to:

Kensington, N.S.W. 2033, Australia ●

SPRING ESHL MEETING

The spring meeting of the Eastern Seaboard Herpetological League will be held on Saturday, 17 March 1984 at the College of William and Mary, Williamsburg, Virginia. The meeting will be sponsored by the Virginia Herpetological Society. All amateur and professional herpetologists are invited to attend the bi-annual meetings of the ESHL, held each March and October.

BRING A LITTLE WILDLIFE HOME . . .

and capture a few salient facts along the way in

A Field Guide to DANGEROUS ANIMALS OF NORTH AMERICA
by Charles Kingsley Levy, Ph.D.

For all the animals you love — and a few you do not — here is the first comprehensive guide to provide detailed information about them all in every category: creatures that envenomate and sting; that bite, maul and claw; and even those that are (or may be) poisonous to eat. For each animal, you will find what symptoms to watch for and what first aid steps are to be taken. This handy field guide is handsomely illustrated with 114 original drawings and 16 pages of color plates. **Paper, $9.95**

Please send me ____ copies of DANGEROUS ANIMALS OF NORTH AMERICA @ $9.95 ea.
I enclose a total of $____.___ in check or money order. I understand you will send these books postage-free with this coupon. Satisfaction guaranteed or my money cheerfully refunded.

ICHTHYOLOGISTS • MAMMALOGISTS • CONSERVATIONISTS • UNIVERSITY RESEARCHERS

VERTEBRATE ECOLOGY AND SYSTEMATICS . . . A TRIBUTE TO HENRY S. FITCH

Special Publication No. 10

Edited by RICHARD A. SEIGEL, LAWRENCE E. HUNT, JAMES L. KNIGHT, LUIS MALARET and NANCY L. ZUSCHLAG

Twenty-four international authorities provide a comprehensive tribute to the natural historian whose outstanding studies have provided the foundation for much of modern ecology.

About 200 pages, with 75 figures, 89 tables and 2 appendices plus index. ISBN 0-89338-019-0. 7 x 10 inches, paperbound.

—CONTENTS—

- **PART I. Introduction**

DUELLMAN Henry S. Fitch in perspective.
V. FITCH A bibliography of Henry S. Fitch.

- **Part II. Reproductive Biology and Population Dynamics**

BROWN & PARKER Growth, reproduction and demography of the racer, *Coluber constrictor mormon*, in northern Utah.
PLATT Growth of bullsnakes *(Pituophis melanoleucus)* on a sand prairie in south central Kansas.
GREGORY Communal denning in snakes.
SEIGEL Parameters of two populations of diamondback terrapins *(Malaclemys terrapin)* on the Atlantic Coast of Florida.
BURKETT An ecological study of the cricket frog, *Acris crepitans*.
PLUMMER Female reproduction in an Arkansas population of rough green snakes *(Opheodrys aestivus)*.
RAND Clutch size in *Iguana iguana* in central Panama.
HALL & MULHERN Are anuran amphibians heavy metal collectors?

- **Part III. Feeding and Behavior**

ANDREWS Energetics of sit-and-wait and widely-searching lizard predators.
GREENE Feeding behavior and diet of the eastern coral snake, *Micrurus fulvius*.
VON ACHEN & RAKESTRAW The role of chemoreception in the prey selection of neonate reptiles.
SHINE Ecology of small fossorial Australian snakes of the genera *Neelaps* and *Simoselaps* (Serpentes, Elapidae).
HENDERSON *Scaphiodontophis* (Serpentes: Colubridae): A natural history and a test of a mimicry-related hypothesis.
CARPENTER Dominance in snakes.
J. FITCH An experimental study of the variation in habitat selection and occurrence of the deermouse, *Peromyscus maniculatus gracilis*.

- **Part IV. Systematics and Biogeography**

WEBB Herpetogeography in the Mazatlan-Durango region of the Sierra Madre Occidental, Mexico.
ECHELLE et al. Systematic review of the percid fish, *Etheostoma lepidum*.
WILLIAMS & DUELLMAN *Anolis fitchi*, a new species of the *Anolis aequatorialis* group from Ecuador and Colombia.

HERPETOLOGICAL ACTIVITIES IN THE PEOPLE'S REPUBLIC OF CHINA

Two recent events have signaled a renewed interest in the study of amphibians and reptiles in mainland China. In 1982 a new quarterly journal, *Acta Herpetologica Sinica*, was initiated, published by the Chengdu Institute of Biology, a division of Academia Sinica located in Chengdu, Sichuan Province, in central China. Technically, this new quarterly is successor to another series of the same name, also issued by the Chengdu Institute but in a pamphlet-length format at irregular intervals (old series, vols. 1-6, 1979-1982). The biological coverage of the new series is quite broad. In the two most recent issues available to me (for March and June 1983) there is an article on the use of electrophoretic techniques to differentiate populations of toads and, in a separate article, use of the same techniques to compare snake venoms; karyotype studies of toads and salamanders; an EM study of intestinal cells of anurans; a study of the physiological ecology of a species of *Agkistrodon;* herpetofaunal analyses of several Chinese provinces; and descriptions of many new genera and species of amphibians and reptiles. A section for short communications is included at the end of each issue. All papers are in Chinese, but each major article has a detailed abstract in English. The format and typography of the new journal are highly professional; drawings are numerous and excellent in quality, and photographs are reproduced separately on glossy paper. Issues measure 18.8 by 26.5 cm and each is approximately 80 pages long. In short, this is a major new herpetological publication, although restricted in geographical emphasis, but nevertheless of broad interest to herpetologists everywhere.

The second event of importance is the establishment of the Chinese Society of Herpetology. This officially took place at Chengdu during the first National Herpetological Congress, sponsored by the Zoological Society of China on 15-20 December 1982. Some 89 people attended this historic meeting, coming from 25 provinces, cities and autonomous regions throughout China. Of 144 papers (60 of which were given orally), 52 dealt with systematics and faunal analysis, 28 were on morphology, 10 karyology, 11 physiology, 23 ecology and 17 on venoms and prevention and cure of snakebite. At the meeting it was decided that future work of the society's members would be centered in four main areas: systematics, morphology, ecology and venomology. The society plans to hold meetings biennially, the next scheduled for Canton in December 1984. Officers of the new society were elected, with Chang Mengwen, author of the book "Amphibiens urodèles de la Chine" (1936), as Honorary President; Hu Shuqin, widow of the well-known Liu Ch'engchao and herself a specialist on amphibians and reptiles, as President; and Ding Hanpo and Zhao Ermi as Vice Presidents. Dr. Zhao was elected General Secretary, in which capacity he is responsible for running the society, and he also serves as Editor of the *Acta*. The society's address is: Chengdu Institute of Biology, P.O. Box 416, Chengdu, Sichuan, People's Republic of China.

A LEATHERBACK RETURNS TO FLAGLER COUNTY: A NEW NORTHERN NESTING RECORD FOR THE U. S. ATLANTIC COAST

The first reliable record of a nesting leatherback, *Dermochelys coriacea*, on the mainland coast of North America occurred on 6 June 1947 at Flagler Beach, Flagler County, Florida (Pritchard, 1971). The event was witnessed and photographed by Ross Allen and party and recorded by Archie Carr in the *Handbook of Turtles* (1952). In the years following, leatherback nestings were reported regularly from the Florida Atlantic coast; there were 11 records in 1957 (Caldwell, 1959). All sightings, however, were from southeast Florida, below Cape Canaveral which is 130 km (80 miles) south of coastal Flagler County.

On 29 May 1983, a leatherback nested, once again, on a beach in Flagler County. The miner's-type head lamps that had dramatically illuminated the 1947 night nesting (10:45 PM, see photographs in Carr 1952) were not needed for this event. The May 1983 turtle, shown in the accompanying figure, emerged in daylight, about 3 PM, near the south boundary of a private beachside campground. The over-curvature carapace measurements were 147 cm in length and 109 cm in width.

As the nesting progressed, a crowd of over 50 onlookers gathered around the turtle. Because egg poaching is traditional in the area, nest relocation was judged necessary by Valinda Ann Nichols, a Florida Park Service Ranger who was at the scene. There were 95 eggs in the clutch, 11 were notably undersized.

The precise location of the 1983 nesting was 4.7 km *north* of Florida Route 100, in the town of Beverly Beach, Flagler County. The 1947 nesting, in the city of Flagler Beach, was approximately 5.5 km *south* of Route 100; hence, a distance of about 10 km separated nestings that occurred 36 years apart. It is impossible that the 1983 turtle was a hatchling of the 6 June 1947 nest; all of the 80 eggs in that clutch were either eaten (pers. comm.) or preserved for scientific study (Carr, 1952). The 29 May 1983 nesting in Beverly Beach is the furthest north on the U.S. Atlantic coast that a leatherback nesting has been definitely documented.

NATURE PRINTS

BY DAVID M. DENNIS

We are pleased to offer four exquisite, full-color art prints by David M. Dennis, naturalist and professional scientific illustrator renown for his watercolors of unusual wildlife.

Plate 1: *Green Frog and Damselfly*
Plate 2: *Painted Turtle and Dragonfly*
Plate 3: *Spotted Salamanders in Courtship*
Plate 4: *Red Salamander and Hercules Beetle*

Prints measure 20 x 24 inches (51 x 61 cm), each signed and numbered by Mr. Dennis in editions limited to only 500 copies. $30 each or $95 for set of four prints plus shipping ($4.50) and any New York taxes.

AN INVENTORY OF PHENOTYPIC ABERRANCIES IN THE EASTERN DIAMONDBACK RATTLESNAKE *(Crotalus adamanteus)*

Color and pattern aberrancies in *Crotalus* have been recorded for many species and occur independently of phylogeny and distribution. Reports are generally more numerous for species that have extensive distributions sympatric with human populations. Phenotypic aberrancies reported for *Crotalus adamanteus* (Hensley, 1959; Leach, 1976; Loftin, 1959; Love and Love, 1979; Murphy and Shadduck, 1978; Shupe, 1977) appear seldom when compared to congeners having comparable demographics: *Crotalus atrox* (Anonymous, 1967; Dyrkacz, 1981; Gloyd, 1958; Holmback, 1981; Karges, 1979; Klauber, 1972; Mitchell, 1974; Nickerson and Mays, 1968), *Crotalus horridus* (Dyrkacz, 1981; Gloyd, 1935; Hensley, 1959; Klauber, 1972; Nickerson and Mays, 1968), *Crotalus viridis* (Chace and Smith, 1968; Dyrkacz, 1981; Gloyd, 1935 and 1958; Hensley, 1959; Irwin, 1979; Klauber, 1972; Nickerson and Mays, 1968; Schuett and Kraus, 1982), and nine albino specimens of *Crotalus durissus terrificus* cited by Klauber (1972). Taxa that have been documented in numbers less than or equal to *C. adamanteus* are: *Crotalus d. durissus* (Villa, 1981; Villa and Rivas, 1971), *Crotalus l. lepidus* (Quinn, 1981), *Crotalus ruber lucasensis* (Gloyd, 1935), *Crotalus s. scutulatus* (Gloyd, 1958; Nickerson and Mays, 1968), and *Crotalus viridis oreganus* (Klauber, 1972; Switak, 1967). Here we note five color aberrant *C. adamanteus* and three other pattern aberrant specimens all from naturally occurring populations. Two of the amelanistic partial albino (Bechtel, 1978; Bechtel, 1980) individuals may have originated from the same gene pool.

Specimen #1. On 22 September 1980 an amelanistic partial albino *C. adamanteus* (Fig. 1) was captured and donated to Santa Fe Community College Teaching Zoo, Gainesville, Florida. The specimen (total length = 715 mm, mass = 242.3 g, total length of five-segmented rattles = 32 mm) was discovered crossing a dirt road in Alachua County, Florida. Scutellation fell within the normal range (McCranie, 1980) for males: 27 dorsal scale rows at midbody; 167 ventrals; 27 subcaudals; 13 supralabials; 18 infralabials.

Three colors are apparent on this specimen: Khaki-tan dorsal diamonds and markings; cream-white ground color; and yellow bordering the diamonds mid-dorsally. The cornea and pupil appear red against a gold iris. The tongue is red. Although the coloration of this specimen is aberrant, the pattern remains normal. This specimen appears hypomelanistic (Bechtel and Bechtel, 1981) and is currently being maintained in captivity for future breeding and histochemical tests (Bechtel and Bechtel, 1980) to determine the etiology of the mutation.

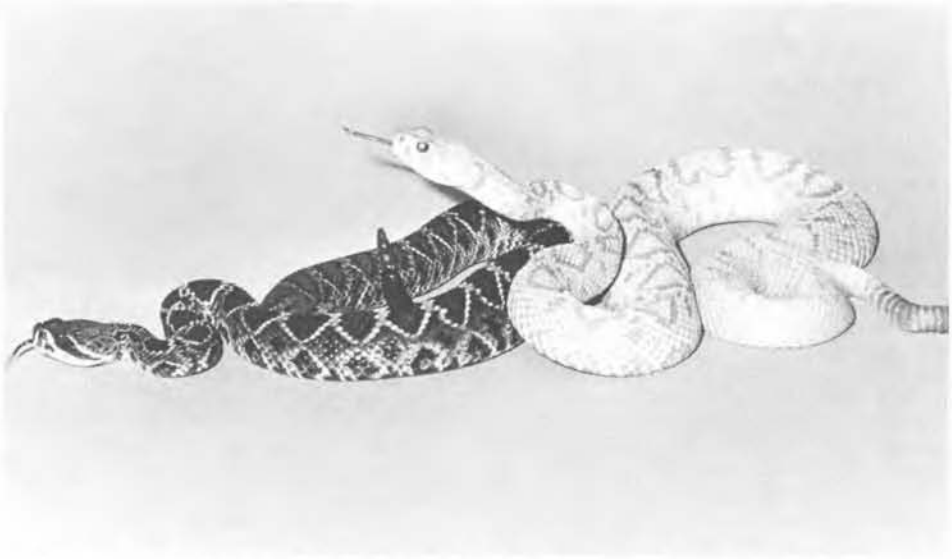

Figure 1. A typical *Crotalus adamanteus* and an amelanistic partial albino (specimen #1 in text). Both specimens are from Alachua County, Florida.

Specimen #2. In January 1973 a decapitated amelanistic partial albino *C. adamanteus* was donated to the Florida State Museum (Peter Meylan, pers. comm). The specimen is now represented only by two 35 mm color slides. This snake appears to have been a young of the year as evidenced by the presence of a button and number 2 rattle (Klauber, 1972). This Alachua County, Florida, specimen exhibits the exact phenotypic aberrancy as specimen #1 and was killed near the same locality.

Specimen #3. An amelanistic partial albino *C. adamanteus* was captured as a juvenile near Tarpon Springs, Pinellas County, Florida, in 1967 (Henry Molt, pers. comm.). This specimen is represented by a 35 mm color slide and appears to have a flesh-white ground color with dorsal diamonds and markings of light yellow and white. The general lack of pigmentation appears more profound in this individual than in the two previously described specimens. The pattern appears to be normal but the eyes are pink.

Specimen #4. On 25 February 1982 a "blue" *Crotalus adamanteus* was captured crossing SR 222 north of Gainesville in Alachua County, Florida. The specimen was donated the same day to Santa Fe Community College Teaching Zoo where it is currently being maintained alive. This specimen was measured (total length = 655 mm, mass = 227 g) on 27 June 1982 and scutellation (McCranie, 1980) fell within the normal range for females: 29 dorsal scale rows at midbody; 177 ventrals; 22 subcaudals; 13 supralabials; 16 infralabials.

This specimen lacks all yellow pigmentation. The resulting colors are reduced to gradations of blue and grey where yellow and brown pigmentation would normally occur on the dorsum. The venter is grey-white. Black pigment remains as it normally occurs and the eyes appear black. Although the pattern is normal the gross appearance is of a very dark individual.

Specimen #5. In April 1981 a blue variant (Vic Morgan, pers. comm.) was captured in Duval County, Florida. This specimen lived six months in captivity and is represented by three 35 mm color slides (Barry Mansell, pers. comm.) of the living individual. The colors in this specimen were almost identical to specimen #4 except they generally appeared to be of a lighter tint, presenting more bluish hues. The eyes appear black. This specimen was apparently a young of the year and exhibited a normal pattern.

Specimen #6. A pattern aberrant *C. adamanteus* (Andrew Koukoulis, pers. comm.) is represented by a color transparency of the living specimen with no further data available. The pattern scheme of this individual is both fragmented and longitudinally fused. Anteriorly the dorsal diamonds are irregularly broken, predominantly along the midline. These nonconforming and asymmetrical fragments indiscriminately fuse anteriorly, but consistently merge posteriorly to form middorsal stripes. These irregularly margined paravertebral stripes involve approximately 75% of the snake's total length, but again abbreviate on the tail to form blotches. Normal *C. adamanteus* coloration is incorporated into this pattern anomaly.

Specimen #7. A mounted pattern-aberrant *C. adamanteus* was examined in the collection of E. A. Griffis. The specimen (total length 0.9 m) was killed approximately 11 km north of Fargo, Clinch County, Georgia, in October 1980 and taken to Mr. Griffis for identification. Scutellation was as follows: 29 dorsal scale rows at midbody; 177 ventrals; 12 supralabials and 16 infralabials (approximated as some scales were obscured in the mounting process); 17 subcaudals (approximated as some obliteration had occurred via a bullet which passed through the tail).

The pattern of this specimen was reduced to a dark middorsal, longitudinal stripe involving 7 scale rows anteriorly and 6 scale rows

posteriorly. Lateral to this dark brown stripe was a lighter yellow stripe to either side involving only one scale row. The remaining dorsal scales were darker than the yellow stripes, but lighter than the middorsal stripe. The tail appeared dark brown and the venter was light brown but darkened posteriorly.

Specimen #8. A mounted pattern-aberrant *C. adamanteus* was examined in the collection of J. Creighton. The specimen (total length 1.3 m) was captured in March 1978 near Plant City, Hillsborough County, Florida, and lived six months in captivity. Scutellation fell within the normal range (McCranie, 1980) for females: 29 dorsal scale rows at midbody; 175 ventrals; 23 subcaudals; 14 supralabials; 15 infralabials.

The pattern aberrancy in this specimen is demonstrated by dorsal blotch fusion at midbody. The striping consists of a brown middorsal stripe of 3 to 5 scale rows bordered on either side by a scale row of black and then a scale row of yellow. These longitudinal stripes comprise approximately 30% of the total body length. The venter is light brown. Normal coloration is present.

In addition to the preceding eight specimens, Mr. Ross Allen (pers. comm.) related to us the occurrence of an albino *C. adamanteus* in 1940 from Ocala National Forest, Marion County, Florida. This specimen was "almost shot in half" and was estimated to be 1.2 m in total length. Mr. Allen also indicated that he had seen two additional specimens exhibiting pattern anomalies, both from Marion County, Florida. The dorsal pattern of these snakes appeared as longitudinal stripes, with one specimen having the stripes present for approximately ½ of the total length while the other exhibited total length striping.

In *C. adamanteus* bicephalism has been reported (Klauber, 1972; Murphy and Shadduck, 1978), but anomalies in color and pattern appear more frequently. In these individuals, the aberrancy occurs either in color or pattern but usually not both. Exceptions are two specimens reported by Loftin (1959) and Love and Love (1979). These two patternless individuals appear solid green or solid white respectively. The anomaly of both color and pattern statistically represents a lower frequency of occurrence than either aberrancy considered singly as color and pattern are inherited separately (Bechtel and Bechtel, 1978). No examples of Gloyd's linked albinism (Chace and Smith, 1968) have been demonstrated in *C. adamanteus*.

Specimens #1, 2, and 3 reported here and the specimen noted by Hensley (1959) are amelanistic partial albino. Deviation of appearance may be due to abnormal melanogenesis and chromatogenesis or different modes of inheritance (Bechtel, 1978; Bechtel and Bechtel, 1981). Specimens #4 and 5 which lack yellow pigment appear similar to the grey individual reported by Leach (1976).

The three pattern-aberrant *C. adamanteus* described in this study (#6, 7, and 8) demonstrate a gamut of paravertebral striping and dorsal blotch fusion which has been previously reported only once in this species (Shupe, 1977). Specimen #6 in this study exhibits a fragmented pattern and presents a most radical departure in paravertebral striping. Specimen #7 shows the more common format of longitudinal striping as does the *C. adamanteus* (UF 48986) reported by Shupe (1977). Specimen #8 which exhibits fusion of the dorsal diamonds at midbody, is peculiar in that longitudinal striping in *Crotalus* usually occurs anteriorly. This dorsal pattern fusion, occurring over a limited area of the body, can not be attributed to geographic variation in the number of diamonds (Christman, 1980).

Paravertebral striping and dorsal blotch fusion appears to be the most common pattern aberrations in *Crotalus* and have been described in *C. atrox* (Anonymous, 1967; Gloyd, 1958; Karges, 1979; Nickerson and Mays, 1968), *C. horridus* (Gloyd, 1935; Nickerson and Mays, 1968), *C. s. scutulatus* (Gloyd, 1958; Nickerson and Mays, 1968), *C. viridis concolor* (Schuett and Kraus, 1982) and *C. v. viridis* (Gloyd, 1935, 1958). Additionally Klauber (1972) mentions specimens of *C. l. morulus, C. t. aquilus, C. r. ruber, C. v. oregonus, C. v. helleri,* and *C. m. stephensi* in which anterior longitudinal stripes were present. Gloyd (1935) regarded this pattern deviation as atavistic to a "striped ancestral stage in the evolution of rattlesnake patterns". The evolution and incorporation of rhombs and diamonds on the dorsum of present-day *Crotalus* implies the advantage of cryptic color and pattern.

Specimens #1 and 2 reported in this study, plus a verbal account of a 1.2 m "white rattlesnake" killed in the same vicinity in 1980, may indicate that this genotype is periodically manifested when chance breeding occurs between two recessive gene carriers. Similar occurrences are documented: two albino *Crotalus horridus* (Ditmars and Toomey, 1923) "captured on the same ledge" at Sheffield, Massachusetts; two striped *Crotalus horridus* (Nickerson and Mays, 1968) "collected no more than 200 yards apart" in Jo Daviess County, Illinois; dorsal blotch fusion in four *Crotalus viridis concolor* (Schuett and Kraus, 1982) from "within an area of ca. 100 m^2." In these populations the frequency of heritable aberrations could be quite high if environmental and gene pool parameters allowed for periodic survival of some individuals to maturation and a higher than normal inbreeding coefficient.

ACKNOWLEDGMENTS

The authors are indebted to H. B. and E. Bechtel for their review of the original manuscript and their many helpful suggestions. In addition to those cited via personal communication in the text, we thank for various courtesies the late R. Allen, J. Creighton, J. Davis, W. H. Gleason, A. Koukoulis, E. Leach, J. R. McCranie, P. Meylan, and J. B. Murphy. Andrew Manis kindly provided the photograph and Lu Ann Antonio typed the manuscript. Upon death specimen #1 and #4 will be deposited in the vertebrate collection of the Florida State Museum.

Authors' Note: On 14 September 1983 a 1.2 m amelanistic partial albino *Crotalus adamanteus* was captured approximately 4.5 km from the locale of specimen #1 in this study. Scutellation (McCranie, 1980) follows that of normal specimens (30 dorsal scale rows at midbody, 176 ventrals, 15 supralabials, 18 infralabials) with the exception of 19 subcaudals which is one less than the low range figure for females. Color follows that of specimens #1 and #2, with 16 dorsal diamonds present. This pattern terminated 25 cm anterior to the vent with the remaining caudal portion patternless. Three distal tail rings occur at the tail tip. Thirteen rattle segments varied little in individual width. The occurrence of this additional specimen supports the existence of a population in Alachua County, Florida which frequently produces this recessive trait.

Another Specimen of *Anarbylus*

Following the appearance of the description of *Anarbylus switakii* in California, (Fritts, et al., J. Herp. 16(1):39), we examined our holdings of *Coleonyx* sp. in the Natural History Museum of California State University, Sacramento, since our herpetology classes have on occasion visited and collected in the areas mentioned. One specimen (RLL 1293, SSC 663) fits Fritts' description. It is a male, 7.6 cm SV, with markings similar to those described, and tail missing. This specimen has been confirmed as *Anarbylus switakii* CAS 156171) by Robert C. Drewes of the Herpetology Department of the California Academy of Science. The lizard was collected from under rocks by Carol Butler and Robert L. Livezey, 12 April 1965, 23.3 miles west of Calexico, Imperial County, California on a dirt road 2.2 miles west of Highway 98 at an elevation of 470-500 feet. The collection of this animal predates the collection of previously reported *A. switakii* by some ten years. Have you checked your jars lately?

A SEA TURTLE NESTING AT ISLAND BEACH STATE PARK, OCEAN COUNTY, NEW JERSEY

In recent years reliable observations have substantiated reports of loggerhead nesting along the Del-Mar-Va Peninsula and the southern New Jersey coast. Confirmed nesting reports are available for Ocean City, Worchester County, Maryland in 1972 (Graham, 1973), Delaware Seashore State Park in 1973 (Mohr, 1973), and Ocean City, Ocean County, New Jersey in 1972 (Anon. 1972).

Several authorities including D. Ehrenfeld (pers. comm.), J. Frazier (pers. comm.), and Conant (1975) concur that sea turtles occasionally nest along the southern New Jersey coastline. But they state that such nestings should be regarded as unusual events, and further studies are needed to determine the actual status of the New Jersey population —if it is a discrete population — and what kind of management program is needed.

The following data are therefore of interest:

On July 29, 1979 at 0300 h a sea turtle was observed nesting at Island Beach State Park, Ocean County, New Jersey. The specimen was observed by John Krejsa, a park ranger. His description of a turtle with a shell length of three and one-half feet or more, brownish in color and having what seemed to be a very large head, strongly suggests that it was a loggerhead, which is indeed the species to be expected.

On August 2, 1979 the nest site was visited by the author and representatives of federal and state agencies. The site, 11.30 m above the high water mark and 47 m from the dune line, was located behind a small rise of sand running parallel with the shore line.

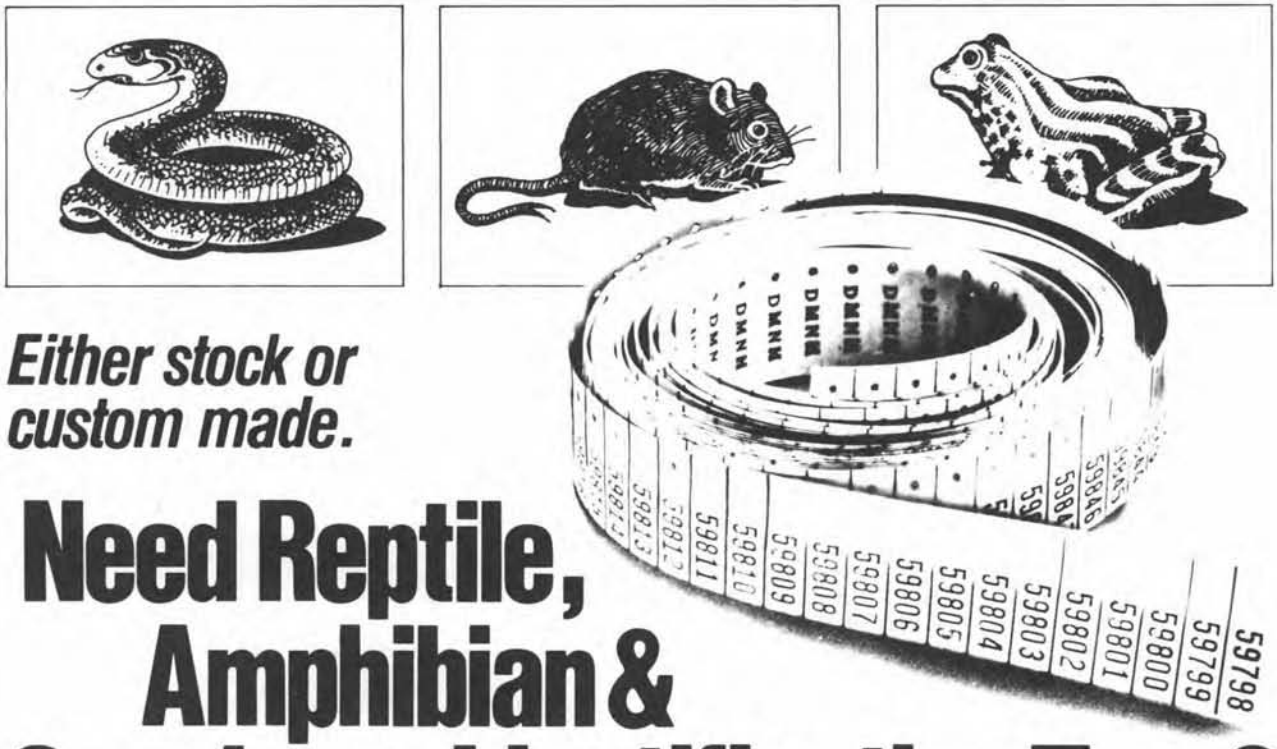
The nest chamber 20 cm beneath the surface was 25 cm in depth, 20 cm in breadth, and contained 129 spherical white eggs averaging 38 cm in diameter.

The number of eggs in the clutch and their size are entirely compatible with figures for loggerheads given by Graham (1973), Mohr (1973), Anon. (1972), and Carr (1952).

The eggs were carefully returned to the chamber and the nest was closed.

Because the eggs had been laid three days earlier and the likelihood of damage was great due to the jostling that would ensue, no attempt was made to remove any for artificial incubation.

Three days later the nest was destroyed by a storm that washed out much of the beach where the nest site was located. Because a management protocol had not been developed in time no attempt was made to save the eggs.



This nesting was 80 km north of the Ocean City, New Jersey site cited by Pritchard (1979) as the northern most latitude recorded for any sea turtle nesting.

LEAST SANDPIPER PREDATION ON *Bufo americanus* AND *Ambystoma maculatum* LARVAE

The quantitative effects of predation on populations of larval amphibians are poorly understood. Several authors (Turner, 1962; Calef, 1973; Cecil and Just, 1979) cite predation as a factor in larval mortality, but do not identify predators or the effects of predation with certainty. The difficulty in accurately censusing larval populations (Turner, 1962) and documenting predation (Turner, 1960) under natural conditions contribute to our lack of understanding. Recent laboratory studies to investigate survivorship have provided some insight (Brockelman, 1969; Calef, 1973). The present report documents predation by the Least Sandpiper *(Calidris minutilla)* on larval *Bufo americanus* and *Ambystoma maculatum*.

On 20 May 1982 I observed 21 Least Sandpipers foraging along the edge of an abandoned gravel pit 2.0 km south of Rockport, Essex Co., Massachusetts. While the flock was feeding several individuals left the group and moved to a shallow pool (2 m x 1 m; maximum depth 3 cm) located 3 m from the gravel pit. On the previous day approximately 360 *B. americanus* tadpoles and 10 *A. maculatum* larvae were censused in this pool. The sandpipers began to feed in an excited fashion, making rapid directed movements into the shallow water with their bills. The activity apparently attracted more sandpipers, until a total of 16 were eventually feeding in the pool. After approximately five minutes, the sandpipers began to disperse and continued foraging along the edge of the gravel pit. An immediate search of the water and substrate revealed no larvae.

In Massachusetts the Least Sandpiper is primarily a coastal species, preferring the extensive flats of salt marshes and beaches. It is also found along inland waterways, particularly those with open muddy shores. The Least Sandpiper is infrequently attracted to the swamps and woodland ponds in which *A. maculatum* and *B. americanus* reproduce. In the present case, however, abundant rainfall during April and May created numerous, ephemeral pools on the sandy flats surrounding the gravel pit, a habitat typically utilized by Least Sandpipers. Some *B. americanus* and *A. maculatum* bred in these shallow pools instead of customary breeding ponds.

Turner (1960) suggests that conditions appropriate for bird predation on amphibian larvae are the result of extreme reductions in water levels. Karlstrom (1954) for instance noted that when Robins *(Turdus migratorius)* fed on *Bufo boreas halophilus* tadpoles, the water was barely deep enough to cover the tadpoles' backs. In this case, reduced precipitation coupled with warm spring temperatures resulted in early drying of breeding ponds. In the present case, drainage and evaporation reduced water levels in the pools, and at the time of predation, water depths were generally less than 2 cm. The large (1-2 cm long) black *B. americanus* tadpoles were conspicuous against the gravel substrate and were easily seen by the birds. Water in these shallow pools disappeared within one to two weeks, indicating that the larvae probably would not have survived.

Although mortality in the present case was complete, the number of *B. americanus* tadpoles and *B. maculatum* larvae consumed represent only 2 to 3% and 0.05%, respectively, of the total populations within the study site (Stangel, 1982, unpublished). Predation by birds on amphibian larvae may be primarily opportunistic, the result of greatly reduced water levels. The effect of avian predation on populations of larvae is probably small, since those larvae most likely to be preyed upon are also highly susceptible to death from desiccation.

TERRESTRIAL MOVEMENTS OF AN EASTERN TIGER SALAMANDER, *Ambystoma tigrinum*

It has only recently become possible to directly follow fossorial, migratory species, such as salamanders, with radioisotope tags (Shoop, 1965, 1968; Shoop and Doty, 1972; Williams, 1973; Douglas and Monroe, 1981; Semlitsch, 1981). Mean distances (47-252 m) traveled by metamorphosing juveniles and adults of five species of ambystomatid salamanders suggest that both adults and juveniles remain near the breeding site once they emigrate. These distances traveled by ambystomatids are shorter than those reported for migrating *Taricha* and *Notophthalmus* (Twitty, et al., 1964, 1966, 1967; Gill, 1979; Healy, 1975).

In this report I add to the data on distance traveled by emigrating, post-breeding individuals and activity centers during the nonbreeding season for *Ambystoma tigrinum*.

METHODS

A terrestrial drift fence of aluminum flashing (440 m circumference) with 40-liter pitfall traps positioned at 10-m intervals completely surrounded a Carolina bay breeding site. A detailed description of the study site, Rainbow Bay, can be found in Semlitsch (1981, 1983). Pitfall traps were checked daily and captured individuals were measured (snout-vent length), sex determined, toe-clipped for individual recognition, and released on the opposite side of the fence.

On 6 March 1982 an emigrating male (No. 353, 102 mm SVL) and female (No. 7029, 98 mm SVL) were tagged with radioactive tantalum-182 wire (1.5 mm X 6 mm, 18 ga, 40±10 μCi). Both individuals were released at 1800 EST approximately 3 m outside the drift fence, adjacent to the pitfall trap where captured. Individuals were monitored with a Ludlum Thyac III survey meter (with a NaI crystal, 4-6 m detection range).

RESULTS AND DISCUSSION

There was 13.4 mm of rain the night of 6

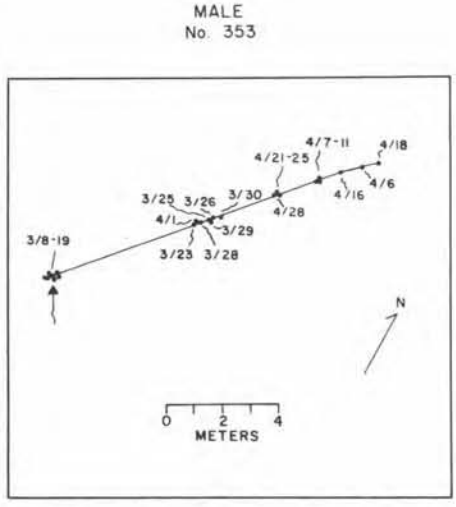

Figure 1. Pattern of movement within the home range of *Ambystoma tigrinum* in South Carolina. Points indicate observations but some observations in the same location are not noted and numbers indicate dates. The arrow indicates the point of entry to the home range from the breeding site.

March and consequently both salamanders moved from their release points. Male No. 353 was found on 8 March, in a pine plantation, 162 m from the release point. Female No. 7029 was lost and not captured at the breeding site again.

The male remained in a relatively small area (12 cm x 37 cm) from 8-19 March (Fig. 1). On 18 March it rained 39.0 mm and between 19-23 March it moved 5.1 m. It remained in the second area (13 cm x 80 cm) until 1 April. Subsequently, between 1-28 April it made several additional moves (1.7-4.6 m). On 28 April the salamander was lost. The wire tag was found in a tunnel, apparently as a consequence of it burning through the skin and falling out.

Between 6 March and 28 April, I excavated the male several times to record its underground location. It was found an average of 12 cm below ground in tunnels averaging 28 mm in diameter.

On 4 November 1982 the male was subsequently captured entering Rainbow Bay and exited the breeding site again on 6 March 1983, 20 m from where it exited a year earlier.

In conclusion, *A. tigrinum* had a similar pattern of terrestrial movement and home range as other ambystomatids studied. Ambystomatid salamanders make several long migratory movements in a few days after emigrating from a breeding site, they remain in burrow systems within a small home range during the non-breeding season, and then reverse their direction of departure 180° to return to the breeding site.

ACKNOWLEDGMENTS

I thank W. Farrell, T. Towns, and R. McFarland for their help in obtaining the radioactive tags and equipment and J. W. Gibbons for commenting on the manuscript. This research was supported by Dept. of Energy Contract DE-AC09-76SR00819 with the University of Georgia (SREL).

A CHARACTER FOR DIFFERENTIATING THE SYMPATRIC LIZARDS, *Anolis cooki* AND *Anolis cristatellus*

Anolis cooki and *Anolis cristatellus* are medium-sized Puerto Rican lizards of similar appearance and habits, with the range of *A. cristatellus* broadly overlapping that of *A. cooki*. *Anolis cristatellus* is ubiquitous on Puerto Rico from sea level to mid-elevations in forest and open habitats, but *A. cooki* is found only in the lowlands of the extreme southwest end of the island (Heatwole, 1976; Williams, 1972). The species are sympatric from the peninsula of Cabo Rojo east to the Reserva Forestal de Guanica and on the islet of Caja de Muertos.

Both species are "trunk" anoles (sensu Rand and Williams, 1969). In sympatry they do not significantly differ in cloacal or preferred body temperatures (Huey and Webster, 1976; Hillman and Gorman, 1977), nor in microhabitat preference (Jenssen, Marcellini, Pague, and Jenssen, unpubl. data). In the field the two species are difficult to distinguish, especially the females and juveniles. Even though *A. cooki* and *A. Cristatellus* are karyotypically distinct (Gorman, Thomas, and Atkins, 1968), there are no diagnostic osteological characters (Pregill, 1981). The reported external morphologic features which have been used to distinguish the species (Table 1) are by themselves equivocal, not applicable to all age and sex classes, or are very difficult to use under field conditions.

While conducting a behavioral ecology study at Cabo Rojo, we found that the tail length (TL) to snout-vent length (SVL) ratio was significantly greater for *A. cooki* than *A. cristatellus*, with *A. cooki* tails being 15-18% longer for a given SVL (Fig. 1). The TL/SVL ratios averaged 2.02 and 1.90 for 111 male and 47 female *A. cooki*, respectively, and 1.67 and 1.62 for 83 male and 43 female *A. cristatellus*, respectively. As long as a lizard had not previously lost part of its tail, the regression relationships of Figure 1 provided an accurate field measurement with which to make species identification.

Table 1. External morphological features that have been used to distinguish *Anolis cooki* and *Anolis cristatellus*.*

Morphologic features	*A. cooki*	*A. cristatellus*
Snout-Vent Length (mm) Mean (Range), No.		
Male	58.6 (29-70), 159	65.1 (25-76), 172
Female	42.2 (25-46), 71	47.3 (30-53), 79
Body Weight (g) Mean (Range), No.		
Male	5.50 (.69-9.70), 132	8.35 (.46-12.40), 159
Female	2.03 (.45-3.70), 69	3.00 (.75-4.0), 75
Scales		
Size of dorsals	Larger (45-68)	Smaller (32-44)
No. of 4th toe lamellae	Low	High
Shape of ventrals	Keeled	Non-keeled
Dewlap color	Orange-red	Orange-yellow

*Weight and snout-vent length data are from Jenssen et al., (unpublished); other features from Gorman, Thomas and Atkins (1968).

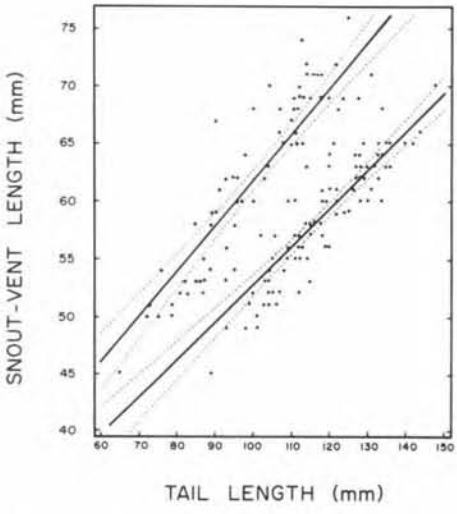

Figure 1. Relationship of snout-vent length to tail length, showing the linear regression lines for 158 *A. cooki* (dots) and 126 *A. cristatellus* (stars). Sex and age classes for each species are combined. Dashed lines give the 95% confidence intervals for the regression lines.

ACKNOWLEDGMENTS

We are grateful to Chris Pague, Lars Jenssen, and Peter Ortiz for their assistance in the field. The data came from a project funded by the Friends of the National Zoo and an Educational Foundation grant from Virginia Polytechnic Institute and State University.

TECHNIQUES

AN ADDITIONAL RESTRAINT TECHNIQUE FOR VENOMOUS SNAKES

Some published restraint techniques for venomous snakes have included the use of a plastic tube for removal of eye caps (Murphy, 1971), and force-feeding (Radcliffe, 1975), and taping of the head for surgery or any other procedure which must restrain the head but leave the reptile's body free. Taping has many problems, however, such as the danger of affixing a piece of tape about a snake's mouth. The animal's fangs may break through the tape, making it dangerous to work too closely to the snake's head. Above all, the snake may experience excessive stress through all steps of this procedure. The method described here was developed while drawing blood samples from snakes via cardiac puncture. It is simple, effective, and inexpensive. This device will reduce the hazards of restraining a venomous snake as well as eliminate much of the stress the animal is subjected to during restraint.

The necessary materials for the construction of this device include a one-quart round freezing container with lid, and a two-and-one-half inch Bulldog paper clip. It is constructed by cutting a hole in the center of the plastic lid with a razor blade. The hole should correspond roughly to the diameter of the snake's neck. Then cut a radius from the hole through the outer ring of the lid. A piece of tape should be put around the hole in the lid to prevent the snake from injury should it struggle while being restrained. Also, cut a rectangular notch one-half inch deep and two-and-one-half inches wide into the upper edge of the bowl portion of the plastic container. The clip will keep the slit in the plastic lid from separating while the snake is restrained, while the notch will accommodate the clip when the body of the container is fitted to the lid.

To place the snake into the restraint device, first pin and pick up the animal. Venomous snakes should be anesthetized at or prior to this point, unless anesthesia will interfere with the subsequent experimental procedures. A second person then places the plastic lid around the snake's neck, wrong side facing forward, separating the lid by pulling upward on one side of the lid and downward on the other (Fig. 1). If the lid is separated by pulling outward, it will have a tendency to crack or split and may pinch the specimen. Once the snake is secured in the lid, the metal clip is placed over the lip of the lid, covering the slit to prevent it from accidentally opening and allowing the snake's head to slip free. The bottom part of the container is then attached, matching up the notch in the container with the metal clip on the lid. The animal can now be placed onto a table for surgery (Fig. 2).

This technique is not without flaws. The device, with the snake enclosed, should be supported until it can be placed on a table. The weight of the container might otherwise cause injury to the snake if it were dropped. Also, it is necessary to pin the snake.

Despite these difficulties, the device has advantages. Since the snake's head is completely enclosed, the container will catch any venom the snake may discharge while restrained. Also, the plastic container is translucent, so the animal can be viewed throughout the procedure. Additionally, once in the restraining device, many snakes will calm down considerably. The reasons for this are currently unknown, but it is easier to work on an animal which does not struggle.

This restraint technique was initially designed for use on viperids. Their distinct heads and relatively thin necks provide less opportunity for slipping through the hole in the lid. The device can be used for snakes of other families, even non-venomous species, but it is most effective on those with a well-defined neck. We have used this method successfully on the following genera: *Crotalus* (6 specimens), *Agkistrodon* (48), *Masticophis* (5), *Nerodia* (19), and *Elaphe* (12). The only species with which we were unsuccessful was *Micrurus fulvius*.

Figure 1. Demonstrating the method of placing the snake's head into the lid of the restraining device.

Figure 2. Once inside the restraining device, the snake should be supported to prevent any injury which could result from the animal thrashing about.

ACKNOWLEDGMENTS

We would like to express our gratitude to Bern W. Tryon for observing the technique, expressing his opinions, and reviewing the manuscript.

A SIMPLE RESTRAINING DEVICE FOR LARGE TURTLES

Handling large, aggressive turtles, such as adult snapping turtles *(Chelydra serpentina)*, particularly under field conditions, can be traumatic for the animal, and potentially dangerous for the researcher. Operations such as counting growth markings on carapacial scutes (Gibbons, 1968; Hammer, 1969; Castanet and Cheylan, 1979), affixing marginal scute tags (Loncke and Obbard, 1977) or radio transmitters (Obbard and Brooks, 1981), require the animal to remain quiet long enough to allow the completion of the procedures accurately. Anesthetization, while now considered fairly safe (Marcus, 1981), requires close supervision over several hours, and professional veterinary training for proper administration, and therefore is impractical for most population ecology studies. Ideally in field studies, captured turtles should be held as briefly as possible before release.

A simple, rugged restraint would greatly facilitate field and laboratory applications of tagging and related activities. Plastic restraint devices suitable for clinical use (Hauser and Mulder, 1981), are difficult to build, and they restrain the animal by clamping over the posterior marginal scutes, making access to these scutes impossible. Other turtle restraints (Graham, 1981), have the disadvantage of obscuring portions of the posterior carapace, and are not suitable for large turtles. Here we describe a simple, inexpensive wooden restraint device suitable for hard-shelled turtles of 15 to 30 cm carapace length. This restraint permits access to the hind limbs and posterior carapace.

The restraint consists of a trapezoidal, plywood head box, and a pair of clamps assembled from plywood and 0.7 cm bolts 9.0 cm in length, secured by wingnuts (Fig. 1). The restraint components are mounted on a 0.62 by 0.58 m piece of 1.5 cm thick plywood, and the whole assembly is painted with waterproof exterior latex paint. Pieces of 5.3 cm wide nylon furniture webbing, 1.0 m in length, are passed under the upper plates of the plywood clamps. Tightening the wingnuts clamps the nylon webbing into place. In use, the clamp on one side of the restraint is tightened prior to placing the animal on the restraint. The other end of the straps may be left loose, to be pulled over the turtle's carapace and through the loose strap clamp once the turtle is in position, or they may be left between the plates of the loose clamp, pulled over the head box, ready to be quickly tightened down.

The turtle is placed into the restraint by angling the body down until the turtle's head is inside the head box, the anterior portion of its carapace in contact with the roof of the head box, allowing the animal to rest on its limbs and plastron on the plywood base. With the head covered, in most cases the animal usually quiets quickly, and will allow manipulation of its hind quarters. The defensive behavior of snapping turtles it to raise the carapace in the direction of perceived threat (Dodd and Brodie, 1975). This defensive reaction tightens the restraining straps. It is necessary, therefore, to allow the animal to settle its plastron against the base of the restraint before finally tightening the clamps holding the straps, otherwise the straps will be slack when the turtle lowers itself from the defensive posture, and the animal will be free to move suddenly.

The straps are secured by tightening the wingnuts on the loose clamp while maintaining tension on the strap by pulling the free end. The operation of the restraint device is speeded by having two people available, one to position the turtle, and one to manipulate the straps and clamps, but we have found that a single person can successfully restrain large snapping turtles with little difficulty after practice. A wide variety of sizes of animal can be accommodated by moving the straps, bolts or wooden clamps, to new positions. Further restraint may be required for delicate procedures or for particularly active animals, and can be provided by additional nylon webbing straps across the midcarapace.

While not autoclavable, and therefore unsuited to clinical use, the ease of construction and use make this restraint ideal for procedures requiring access to the posterior portions of a large turtle's carapace, or procedures requiring the turtle to remain motionless for an extended period.

ACKNOWLEDGMENTS

We wish to thank William Galbraith for his assistance in the design and fabrication of the prototype restraint device, and James Malcolm and an anonymous reviewer for their constructive criticisms of earlier drafts of this paper.

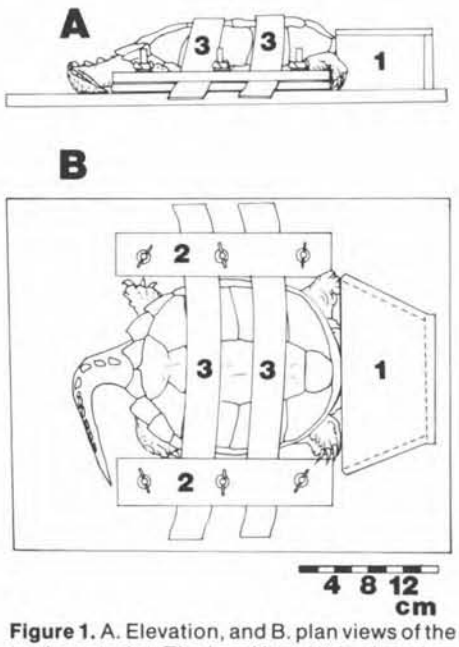

Figure 1. A. Elevation, and B. plan views of the turtle restraint. The head box (1) is closed on three sides, above and below, and opens toward the center of the plywood base. The two strap clamps (2) are pieces of plywood, held together by wingnuts. Nylon furniture webbing (3) is passed between the plates of each clamp to span the distance between them, over the turtle's carapace.

A TECHNIQUE FOR PARTITIONING HATCHING AND MORTALITY ESTIMATES IN LEAF-BREEDING FROGS

The estimation of mortality of the early developmental stages of anurans is a difficult problem in population biology. Despite a rapidly expanding literature on the population ecology of post-hatching and post-metamorphic anurans, Turner's (1962) statement that virtually no data exist on embryonic mortality in nature is still fairly accurate. Bragg and Bresler (1951) estimated survival of *Bufo cognatus* embryos by considering empty capsules to be viable, hatched eggs. More recently, Howard (1978) estimated embryonic mortality in *Rana catesbeiana* by periodically removing small samples from monitored clutches. Mindful of the problem of monitoring the larger clutch sizes associated with many temperate anurans, Turner (1962) suggested that opportunities for assessing early mortality are excellent in the tropics, where many species deposit small egg

clutches, which make direct counts feasible. Greer and Wells (1980) measured clutch mortality directly by counting the eggs of *Centrolenella fleischmanni*. M. Crump (pers. comm.) measured prehatching survivorship in the leaf-breeding hylid, *Hyla bokermanni*, by counting remaining embryos over short time intervals and by scanning nearby litter for larvae unable to reach the water. Unfortunately, these methods require assumptions which often seriously compromise mortality estimates or are so time consuming that obtaining adequate sample sizes is often unfeasible. Therefore, I describe here a unique method of estimating prehatching survivorship which is potentially useful on any frogs utilizing aerial clutch deposition sites under which the described apparatus can be positioned (e.g. Neotropical phyllomedusine hylids, *Hyla ebraccata*, hylids in the *Hyla parviceps* group (Duellman and Crump, 1974), most centrolenids, many Old World rhacophorids and hyperoliids, and *Litoria iris* from New Guinea). This technique permits: 1) effective partitioning of hatching and mortality estimates with minimal assumptions, and 2) application to a large sample size over a short period of time.

The method utilizes a cup placed beneath the clutch whose survivorship is to be monitored (Fig. 1). We used a seven fluid ounce #806A COZY cup (Solo Cup Co., Urbana, Illinois 81601) because it was readily available and lightweight (ca. 6 grams). However, any inexpensive lightweight cup of approximately the same size would be satisfactory. I suspended cups with malleable copper wire. The wire should be light enough to avoid weighing down the leaf, but firm enough to provide a secure attachment. Twenty-four gauge wire was suitable for this purpose. In cases where the additional weight to the clutch substrate proved a problem, I sank wooden dowels (1.3 cm diameter - lengths variable) from which the cups were suspended into the streambank. A circular wire basket (Fig. 1B) suspends the cup in a vertical position. A small wire loop (Fig. 1A) secures the cup to this suspension basket and allows the investigator to empty the cup with little disturbance to the suspension. The entire apparatus is secured by a wire (Fig. 1D) extending from the basket itself to the substrate of the monitored clutch, or to a dowel or some other stable object. The cup has an overflow drain (Fig. 1C) which releases rainwater in excess of that necessary to keep recently hatched larvae alive. This drain consists of a ring of small holes (ca. one millimeter in diameter) punched about six millimeters above the base of the cup. Holes should be large enough to drain the cup effectively and avoid weighing down the clutch substrate, yet small enough to prevent the loss of hatched larvae.

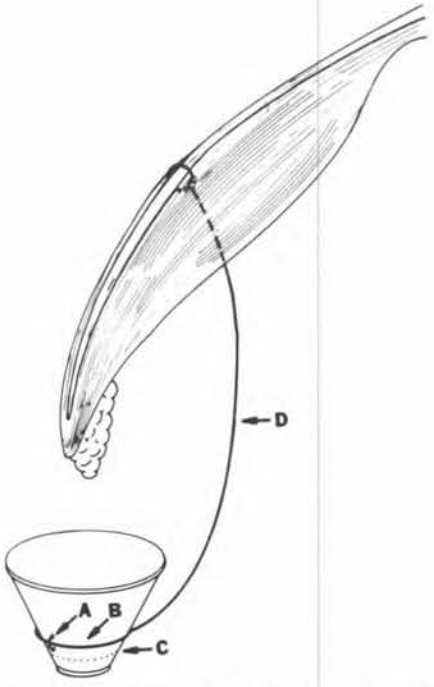

Figure 1. Hatching cup positioned for monitoring survivorship in a clutch of *Centrolenella fleischmanni* (diagrammatic). A. Securing wire loop B. Suspension loop C. Overflow "valve" D. Attachment wire

The "hatching cup" catches recently-hatched larvae as they fall from the monitored clutch. When hatching of a monitored clutch began, I emptied the cup of larvae once daily until the entire complement had hatched. The difference between the number of larvae caught by the cup and the initial egg count for a clutch is a direct measure of mortality in that clutch.

During 1980 and 1982, I used this technique to measure mortality in nearly 300 clutches of populations of the glass frog, *Centrolenella fleischmanni*, in Monteverde, Puntarenas Province, Costa Rica. Once cups were positioned, I was able to effectively monitor 30-50 clutches daily in less than an hour. The technique failed in only four cases. In each case, error could be attributed to dislocation of the cup suspension: three were displaced because wind tore the suspension from a frail substrate, and one because the cup and its suspension collapsed after its substrate was swept away by rising stream water.

I was also concerned about the possibility that the cup apparatus itself might affect the clutch environment by somehow influencing the pattern of mortality in monitored clutches. This effect is important if one wishes to assess patterns of mortality in a population by generalizing from a sample of monitored clutches, but it would be unimportant in comparisons between samples of clutches all monitored with this technique. I tested the effect that cup proximity might have by comparing 12 pairs of equal-sized clutches. One clutch of each pair was monitored with a gallon jug placed on the ground (or stream edge) beneath the clutch. Pairs were selected for similarity of their clutch deposition sites, particularly with respect to surrounding and overlying canopy, and at approximately equal heights above the substrate. Two pairs were eliminated from the comparison because disturbance resulted in loss of larvae part-way through the monitoring period. I was unable to reject the hypothesis of equal mortality between cup-monitored vs. jug-monitored clutches (X^2=0.54; $p>0.05$), which suggests that the proximity of the cup had no effect on the pattern of mortality observed in monitored clutches. However, future investigators are cautioned to consider cup proximity in context of the existing predator set. One should insure that proximity does not facilitate access or visibility to clutch predators, and that small predators do not remove larvae that have hatched into the cup. I was able to test the latter of these possibilities during 1982 by placing small cellophane funnels in the hatching cups monitoring 20 clutches in a manner that prevented access by small arthropod predators, but larval hatching into the cup was unimpeded. A comparison with 20 equal-sized control clutches under similar conditions showed no differences in the mortality patterns of clutches (X^2=3.22; $p>0.05$), which suggests that removal from the cups was an unimportant source of error in the population being studied. However, at this site, observed predators were few (Hayes, 1983) and predation levels were low (Hayes unpubl. data). This implies that a site-specific test of this effect is necessary, because high predation levels will skew mortality estimates. This is a basic consideration because the method is potentially most useful where mortality from clutch predators is high.

ACKNOWLEDGMENTS

The idea for this technique was developed during the Organization for Tropical Studies (OTS) course 79.3 and executed during 1980 under a RIAS grant from OTS. Work in 1982 was supported by an NSF doctoral dissertation improvement grant (DEB-8200275). The Allan Hancock Foundation at the University of Southern California also supported the work in part. C. Guyer deserves special thanks for suggesting the addition of the overflow drain to the cups. D. Krempels drew the figure. M. A. Donnelly, C. Guyer, D. M. Krempels, M. M. Miyamoto, M. J. Rosenberg, J. M. Savage, S. D. Werman and an anonymous reviewer provided suggestions on the manuscript.

NEWSNOTES

REPOSITORIES SOUGHT FOR CONFISCATED SNAKES

The Management Authority of Hong Kong would like to know the name and address of any institution which might be interested in looking after live snakes of endangered species, especially *Python* species, which might become available in the course of enforcement in relation to CITES.

Interested institutions, which are expected to pay for the transport costs, are invited to contact the Hong Kong Management Authority, either directly (see the Directory under United Kingdom) or through the Secretariat, c/o UICN, avenue du Mont-Blanc, CH-1196 Gland, Switzerland. ●

SCIENCE SOFTWARE NEWSLETTER

The Center for Environmental Studies at Arizona State University is interested in publishing a newsletter dedicated to computer (particularly microcomputer) software and applications for the natural sciences. The newsletter would be published quarterly and would contain 1) a listing and short review of recent scientific software, with availability and compatibility specifications; 2) one or more articles on microcomputer techniques — how to download software for different systems, how to choose between a minicomputer and a network of micros, etc.; 3) a forum for advertising "custom" software — a place where scientists who have written software for specialized modeling or applications (for microcomputers, minis, or mainframe) can list and describe programs for free use, exchange or sale. We are currently assessing the level of interest in such a publication among the scientific community, as an aid to obtaining necessary funding. If you are interested in seeing such a publication, would like further information regarding it, or would be willing to serve as a reviewer for new software and documentation, please call or write me at the address below.

LSU - NIH ALBINO BULLFROG

The Louisiana State University Amphibian Culture Facility, with support from the Research Resources Division of NIH, LSU Sea Grant, and the Louisiana Agricultural Experiment Station has been operating since 1968 in developing management procedures for *Rana catesbeiana*.

The functions of the facility are to (1) develop laboratory and commercial-scale culture facilities, (2) define and implement culture technology for sustained maintenance of defined strains through successive generations, and (3) develop high quality lines of *Rana catesbeiana* for use in research. The laboratory has been involved in establishing culture systems in universities, medical schools, zoological parks, and private industry internationally.

For the past three years the facility has worked to develop an albino colony of bullfrogs. The colony is now well established and the numbers exceed our capacity for maintenance. We are therefore searching for people with appropriate facilities to accept, maintain and establish a small breeding population. Anyone with the capability and interest in long-term management of a colony should contact the facility. Information concerning culture methodology will be provided.

ASSOCIATION OF PACIFIC SYSTEMATISTS

At the Association of Systematics Collections (ASC) annual meeting in Honolulu in May 1982, members and invited participants at the ASC symposium proposed the formation of an association of Pacific systematists, to be further discussed in 1983 at the XV Pacific Science Congress. On 9 February 1983, at the XV Pacific Science Congress in Dunedin, the audience of systematists at the Symposium on Biological Collections in the Pacific unanimously resolved that an Association of Pacific Systematists be formed.

Mr. J. S. Dugdale was named as interim President and Dr. S. H. Sohmer as interim Secretary-Treasurer.

We are now soliciting membership in the Association, and we hope that this communication will elicit response from those who had originally indicated interest and others who have not yet had the opportunity to do so. Annual dues have been set at U.S. $5.00. The Association will be an organization for and of systematists in the Pacific. News concerning research efforts and opportunities in the Pacific will be a prime focus. The first tangible result of membership will be a Newsletter. The dues will help defray the cost of handling and mailing.

The initial aims of APS are:

1. to promote and facilitate communication among Pacific systematists including producing and distributing a newsletter,
2. to represent Pacific systematists as a group with respect to opinions on relevant issues,
3. to carry out other functions as may be considered desirable.

Please write and send membership dues to:

SAPO NATIONAL PARK IN WEST AFRICA LIBERIA'S FIRST NATIONAL PARK

Sapo National Park is the first to be established of three proposed national parks and four nature reserves selected in late 1978 and early 1979 with the assistance of the I.U.C.N. and the World Wild Life Fund. The park is situated in southeastern Liberia and covers a total land area of 505 sq. miles of primary lowland rainforest. Sapo is 440 miles, by road from Monrovia, Liberia's capital city. There are also regular local air services from Monrovia to Greenville in the South and to Zwedru in the North. The park is not yet penetrated by motor roads.

The new national park supports species of large and small mammals which are also distributed throughout the forest region of the country. Over ten species of primates are found in Sapo. Many species of reptiles and approximately 300 species of birds also inhabit Sapo.

The Park is presently protected by a staff numbering twenty-two. Four are trained Liberian graduates of the College of African Wildlife Management in Tanzania, two are U.S. Peace Corps volunteers and the others are ex-hunters and farmers who are well-acquainted with the forest environment in that part of the country.

The official establishment of Sapo National Park in May 1983 is a major breakthrough for wildlife conservation practices in Liberia and its development may stimulate the creation of the other national parks and nature reserves. Emphasis in the early management of the park is being placed on research on the biological resources of the region, under the direction of the Forestry Development Authority.

EPA PUBLISHES ENVIRONMENTAL EVENTS CALENDAR

The U.S. Environmental Protection Agency Region V will once again publish an Environmental Events Calendar, to appear on the 1st and 15th of each month and distributed free to all interested parties.

The calendar will list meetings, hearings, seminars, workshops, conferences and other environmentally-oriented events in EPA Region V (Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin). All sponsoring organizations are invited to send pertinent information, including contact person, to:

R. John Rapsys, Editor
Environmental Events Calendar
Office of Public Affairs, 5PA-14
U.S. EPA Region V
230 S. Dearborn Street

ERRATUM

Please note the following correction in the feature article "Morphologic evidence of toxic saliva in colubrid snakes: A checklist of world genera," by Donald M. McKinstry (Herp. Review 14(1):12-15). In Table 5 "Duvernoy's Gland Type[53]" *should read* "Gland Type[53]." ●

Publications Exchange Sought

Because of currency restrictions, herpetologists in certain countries cannot purchase SSAR membership. These persons often seek to exchange an SSAR membership for subscriptions to periodicals which they can purchase. The editors have been advised of one such person who wishes to exchange the journal *Aquarien Terrarien* for an SSAR membership paid in his name. Persons interested should correspond with:

Herbert Rössler
Ferdinand-Freiligrath Strasse 51
DDR -4308 Thale (Harz)
German Democratic Republic ●

TRITURUS GROUP FORMING

For some time it has been clear to us that there are many people in Europe, and some in America, who are actively working on European newts, but that many of us know little or nothing about one another's interests. To rectify this situation, we have invited a number of workers to participate in an information service designed to enable *Triturus* enthusiasts to communicate and collaborate with one another. We feel that better communication is important at this time because we have found that previously disparate studies of *Triturus* show great promise of coming together to provide a detailed understanding of the biology and evolutionary history of the genus.

We have so far sent out 65 letters and questionnaires and have, to date, received 41 replies. We are very encouraged by the enthusiasm with which this scheme has been welcomed.

In June or July of 1984, it is hoped to hold a conference on the Evolutionary Biology of *Triturus*, to be organised by Professor Herbert Macgregor and Dr Tim Halliday at Leicester University, England.

Anyone interested in the *Triturus* information scheme or in this conference should contact:

Tim Halliday
Department of Biology, The Open University
Milton Keynes MK7 6AA, England ●

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Houston Zoological Gardens, P.O. Box 1562, Houston, Texas 77001.

ANURA

ACRIS CREPITANS BLANCHARDI (Blanchard's Cricket Frog). **ANOMALIES.** We report on two specimens of *Acris crepitans blanchardi* with anomalous characters. The first, taken on 15 October 1973 at Lake Lotawana, Jackson County, Missouri, lacked the left eye and orbit (Figure 1). This was apparently a congenital defect.

The second specimen, taken on 17 April 1982 along Shoal Creek, 3 km NNW of the junction of I-44 and MO Hwy 43, Newton County, Missouri, had a bloated appearance (Figure 2). The skin of this specimen was dissected back, and it was found that the bloated condition was due to gas released into the subcutaneous area, distending the skin. The gas apparently emanated from a herniated portion of the small intestine at the right lateral lumbar region. The herniation was probably induced by trauma at the time of capture. The bloated condition was first observed about an hour later and superficially resembled hydrops - an excessive accumulation of fluids in the subcutaneous lymphatic spaces, as pictured in *Xenopus laevis* in Elkan and Reichenbach-Klinke (1974. Color Atlas of the Diseases of Fishes, Amphibians and

Figure 1. *Acris crepitans blanchardi* from Jackson County, Missouri, lacking left eye and orbit.

Figure 2. *Acris crepitans blanchardi* from Newton County, Missouri, with bloated appearance due to the accumulation of gas in the subcutaneous region.

Reptiles. T.F.H. Publ., Inc. Ltd: p 191, fig. 300). In reality the malady is similar to that reported for *Triturus vulgaris* (Elkan, 1960. Some Interesting Pathological Cases in Amphibians. Proc. Zool. Soc. Lond., 134:275-296), except that in the *Acris*, the gas from the herniated intestinal tract was escaping into the subcutaneous area. In the *Triturus*, the gas from the fermentation of stomach contents expanded the stomach through the thoracic wall as well as the overlying skin.

The first specimen of *Acris* was deposited in the vertebrate collection of the University of Missouri - Kansas City, but has been lost. The second specimen is deposited in the Bobby Witcher Memorial Collection (BWMC 2027), Avila College, Kansas City, Missouri.

Submitted by **DONALD D. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th St. and Rainbow Blvd., Kansas City, Kansas 66103, and **ROBERT POWELL,** Department of Natural Sciences, Avila College, 11901 Wornall Rd., Kansas City, Missouri 64145, U.S.A. ●

SAURIA

EUMECES SEPTENTRIONALIS (Northern Prairie Skink). **AGONISTIC BEHAVIOR.** Intraspecific aggression has not been reported for *Eumeces septentrionalis* (Ferguson. 1977. pp. 265-334 *in:* Gans, C. and D. W. Tinkle, eds. Biology of the Reptilia, Vol. 7. Ecology and Behavior), with the exception of cannibalism of young by adults (Breckenridge. 1943. Amer. Midl. Nat. 29:591-606). Stamps (1977. pp. 265-334 *in:* Gans and Tinkle, op. cit.) pointed out that exclusive occupancy of burrows by individuals of this species does not necessarily imply active site defense (Breckenridge, op. cit., was cited in regard to exclusive burrow occupancy but contains no mention of this topic). The purpose of this paper is to report observations of agonistic behavior by captive prairie skinks.

Two adult *E. septentrionalis* were collected in western Hennepin Co., Minnesota in 1978. Skink A, captured 23 May, is still alive at present and is presumably a female based on lack of orange chin coloration at the time of capture. Skink B, slightly shorter and more slender than A, was captured 23 August; unfortunately this specimen was disposed of without being sexed when it was discovered dead of unknown causes on 24 May 1981. The skinks were maintained in a glass cage 56 cm x 30.5 cm x 31.8 cm with a substrate of wood chips, a wooden box and rock slabs for shelter, and a water dish. An incandescent bulb was positioned outside one end of the tank to provide warmth, and a diet of *Tenebrio* larvae and assorted small invertebrates was supplied.

For some time the two skinks were not observed to interact, although they often basked in close proximity or actual contact and they were sometimes found in close proximity beneath the same shelter. Early interactions were associated with feeding and usually occurred shortly after the introduction of food into the cage. Sudden movements by one individual discovering and ingesting a prey item would stimulate the other skink to begin foraging in the same area or contest the same prey item (see Greenberg. 1976. Herpetologica 32:349-352). Attention seemed focused on food rather than the conspecific. This focus seemed to shift during later interactions:

23 September 1979 - B made repeated lunging attempts at removing a prey item from A, caused A to retreat, and then made several lunges at A's tail. Later, when B was chasing a prey item, A approached from the rear, apparently interested in the same item. B turned toward A and A retreated.

14 October 1979 - A attempted to remove a prey item from B.

12 March 1980 - A tugging match, with A and B at either end of a *Tenebrio* larvae.

18 April 1980 - Mutual snapping at conspecifics' heads during feeding, interlocking of jaws, and brief struggle.

22 April 1980 - Shortly after introduction of food, A bit tail of B and chased B around the cage perimeter. Later, after introduction of another prey item, B began biting at neck of A and occasionally at A's side or tail, but because of smooth scalation, was not able to get a good grip. When biting, B approached A perpendicularly from the side. A occasionally snapped back, turning so that it was facing B perpendicularly from the side. Later, A initiated aggressive behavior against B after B made a sudden motion similar to a feeding lunge.

The observations reported here are admittedly nonquantitative and occurred in an artificial setting. They nevertheless demonstrate the existence of agonistic actions in the behavioral repertoire of *E. septentrionalis*. It is interesting that neither skink established a clear dominance over the other.

Submitted by **PHILIP A. COCHRAN,** Center for Limnology, University of Wisconsin, Madison, Wisconsin 53706, U.S.A. ●

SERPENTES

CEMOPHORA COCCINEA COPEI (Northern Scarlet Snake). **COLORATION AND REPRODUCTION.** An amelanistic partial albino *Cemophora coccinea copei* was received by the AZP 30 June 1983 for identification. The snake was found and killed by Mrs. L. M. Scarborough 6.5 km N of Riverdale, Clayton County, Georgia, 9 June 1983 at 1015 hr; air temperature was ca. 26° C. Upon death, the snake was placed in 70% isopropyl alcohol. The snake, an adult female 280 mm total length (S-V = 230.5 mm), had nine fully developed eggs ($\bar{x}$ = 14.2 mm) in the oviducts. Wright and Wright (1957. Handbook of Snakes of the United States and Canada, Cornell Univ. Press. Vol. 1, p. 114) reported on an albino *Cemophora* from North Carolina, although this reference was overlooked in the reviews of Hensley (Mich. State Univ. Biol. Ser. 1 [4]) and Dyrkacz (1981. SSAR Herp Circ. 11). The coloration, in alcohol, conforms to that cited by Wright and Wright (1957, p. 114) with 18 reddish-pink body saddles and three tail saddles. Wright and Wright (1957, p. 115) reported 3-8 eggs for *Cemophora*, so the nine eggs reported herein would constitute a maximum clutch record for the species. The preserved snake and eggs will be deposited in the vertebrate collection of the Museum of Natural History, University of Georgia.

DIADOPHIS PUNCTATUS ARNYI (Prairie Ringneck Snake). **COLORATION.** An acarotenoidic *Diadophis punctatus arnyi* was captured, along with four normally pigmented individuals under the same rock, at Drywood Creek along MO Hwy 43, 9.5 km S. of the Vernon County line, in Barton County, Missouri, on 18 April 1982. The specimen, a male measuring 273 mm in total length, lacks nearly all orange, yellow, and red pigmentation typical of the subspecies. In life, the nuchal collar was obscure with only a trace of orange pigmentation being visible (Figure 1). The venter totally lacked carotenoid pigments and was light metallic gray, patterned irregularly with small black spots (Figure 2). The specimen has been deposited in the Bobby Witcher Memorial Collection (BWMC 1750), Avila College, Kansas City, MO.

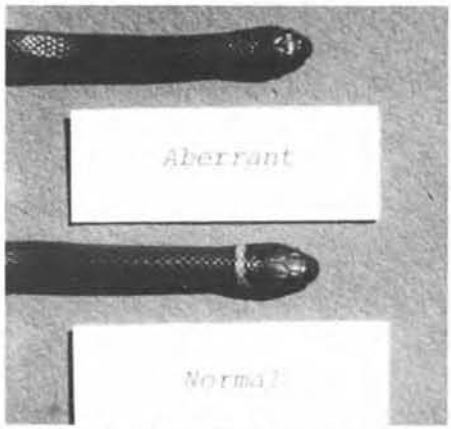

Figure 1. Nuchal areas of BWMC 1750 and a normal *Diadophis punctatus* from Barton County, Missouri.

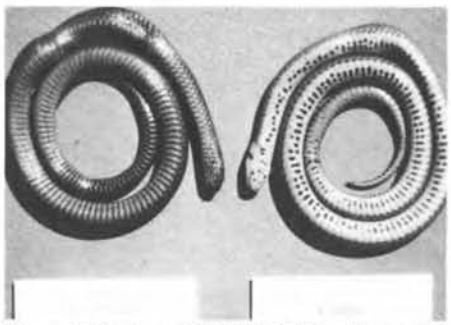

Figure 2. Venters of BWMC 1750 and a normal *Diadophis punctatus* from Barton County, Missouri.

Snakes lacking carotenoid pigments are not unknown, although most reports are probably camouflaged as "partial albinos." Dyrkacz (1981. Recent Instances of Albinism in North American Amphibians and Reptiles. SSAR, Herp. Circ. No. 11) cited four occurrences of albinism for *Diadophis punctatus*. At least two of these (Groves, 1974 and Bryant, 1974) were amelanistic, but still retained some of the yellow coloration of carotenoid pigments. A third specimen (Bradshaw, 1966) lacked virtually all pigmentation, being both amelanistic and acarotenoidic. Other examples of snakes lacking carotenoid pigments include two *Farancia a. abacura* with white venters (Wright and Bishop. 1915. A Biological Reconnaissance of the Okefinokee Swamp in Georgia, Part II. Snakes. Proc. Acad. Nat. Sci., Phila., Vol. 67:139-192), and a specimen of *Carphophis amoenus* (BWMC 1266) from Macon County, North Carolina, which in life lacked the pink ventral coloration typical of that species.

Submitted by **MARTIN L. JOLLEY** and **ROBERT POWELL,** Department of Natural Sciences, Avila College, 11901 Wornall Rd., Kansas City, Missouri 64145, U.S.A., and **DONALD D. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th St. and Rainbow Blvd., Kansas City, Kansas 66103, U.S.A. ●

DRYMARCHON CORAIS CORAIS (Yellowtail Cribo) **REPRODUCTION.** Amaral (1976. Brazilian Snakes: a Color Iconography. Melhoramentos) gives the clutch size as 8 to 12. Whitecar (1983. personal communication) gives 24 as the largest clutch size he observed in captivity. On 27 March 1983 the author's specimen deposited a clutch of 27 nonadherent eggs of which 20 were fertile. Two infertile eggs were also subsequently passed 19 May and 24 May. This clutch, taken as 27 or 29, represents the largest reported for this taxon.

Submitted by **HENRY COHEN,** 24 St. Johns Pl., Buffalo, New York 14201, U.S.A. ●

ECHIS COLORATA (Palestine Saw-scaled Viper). **WATER ECONOMY.** Since 1971, hatchlings from 17 clutches of *E. colorata* eggs have been maintained for varying periods of time in the Columbus Zoo. It has been observed that neonates feed more readily when kept under drier conditions and higher temperatures than those suited to many other forms. In 1981, hatchlings from three clutches were housed from date of hatching in individual containers, and kept at approximately 32° C. In an effort to provide dry conditions, the animals were kept on a substrate of #16 sieve sand, and provided with no access to standing water. The original plan was to have provided water bowls at intervals as the animals seemed to require them. No such requirement has yet been evident. The original group has been reduced to five, although no deaths have occurred while in the conditions described. Other animals have been removed from the collection through sale, trade or breeding loan to other institutions. The five animals retained in the collection (three hatched 1-5 July 1981, two hatched 28 June 1981) have now been maintained without access to standing water for a period in excess of 665 days. The animals have been fed one or two appropriately-sized mice at 7-21 day intervals. Growth has exceeded that of previously reported progeny, which were maintained at lower temperatures (Goode. 1979. Herp. Review 10(3)). Ecdysis and waste elimination have also been consistent with that of other progeny of the species in this collection.

Submitted by **MIKE GOODE,** Columbus Zoo, Columbus, Ohio 43065, U.S.A. ●

LAMPROPELTIS CALLIGASTER CALLIGASTER (Prairie Kingsnake). **COLORATION.** During the summer of 1978, one of us (B.C.) obtained an amelanistic *Lampropeltis c. calligaster* collected in Kansas City, Wyandotte County, Kansas. It is a partial albino with xanthophores, and exhibits pink eyes, a ground color of creamy white, and a hint of normal pattern with slightly more yellowish coloration (Figure 1). The specimen is a male, and at this time measures about 122 cm in total length. In a review of albinism (Dyrkacz, 1981. Recent Instances of Albinism in North American Amphibians and Reptiles. SSAR, Herp. Circ. 11:31p), albinistic *L. calligaster* were listed from Georgia (Collins, 1960) and several from Texas (Reported by J. B. Murphy).

Figure 1. An amelanistic, partially albinistic specimen of *Lampropeltis c. calligaster* exhibiting trace of pattern at time of shedding. Wyandotte County, Kansas.

The specimen from Kansas was loaned to the Dallas Zoo from February 1979 through February 1983 in an unsuccessful attempt to breed it with one of the specimens from Texas. It is currently back in the private collection of its owner, but further attempts will be made to enter it into a breeding program. Upon death, the specimen will be deposited in the Museum of Natural History, University of Kansas, Lawrence.

Submitted by **BOB CLARK,** 2501 West Memorial Rd., Suite 111, Oklahoma City, Oklahoma 73120, **ELIZABETH I. SMITH,** 1319 South Pearl St., Independence, Missouri 64055, and **DONALD D. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th St. and Rainbow Blvd., Kansas City, Kansas 66103, U.S.A. ●

LAMPROPELTIS MEXICANA THAYERI (Gray-banded Kingsnake). **COLORATION.** A melanistic *Lampropeltis mexicana thayeri* was hatched from a clutch of 5 eggs on September 5th, 1982. The remaining 4 hatchlings exhibited normal coloration. The parents were siblings of a brood of 8 normal patterned offspring from an adult melanistic female and normal patterned male, the original collected stock. This stock was collected in the Galeana area of Nuevo Leon, Mexico.

The melanistic offspring is overall black (including eyes) with underlying *"leonis"* type banding evident when held up to light. It is behaving normally and readily feeding on lizards *(Eumeces)* and pink mice.

Considering the 1:4 ratio of the F_2, and based on several other wild caught and captive bred melanistic specimens I am aware of, it would seem that this trait fits the classic Mendelian 1:2:1 ratio. Further reproduction, such as melanistic to heterozygous melanistic, will be carried out for more understanding of the recessive trait. One point of interest is that of the few *L. m. thayeri* that have been collected, several have been melanistic. The speciman was determined to be a male and is being maintained in the collection of the author.

Submitted by **STEVEN T. OSBORNE,** Animal Technician in Herpetology, Oklahoma City Zoo, Oklahoma City, Oklahoma 73111, U.S.A. ●

NERODIA ERYTHROGASTER TRANSVERSA (Blotched Water Snake). **REPRODUCTION.** The Pathology Museum of the University of Kansas Medical Center, Kansas City, Kansas, has in its possession an exhibitory preparation containing the heads and neck regions of an adult and 28 newborn *Nerodia erythro-*

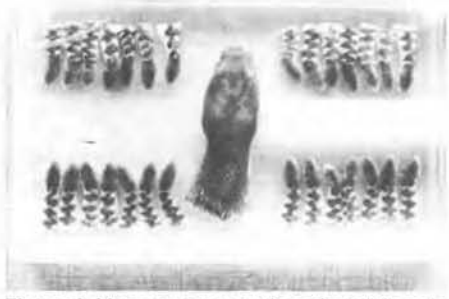

Figure 1. Museum preparation of adult female and 28 newborn *Nerodia erythrogaster transversa* from Linn County, Kansas.

gaster transversa (Figure 1). The adult was shot at a farm pond, 13 km North of Pleasanton, Linn County, Kansas, by David V. Connell (Pathology Museum Curator, Retired) in September 1973. Most of the juveniles were collected in a large tub as they exited the body, apparently stimulated to activity and birth by associated trauma. Prior to fixation the female was dissected to obtain all of the litter.

Fitch (1970. Reproductive Cycles of Lizards and Snakes. Univ. Ks., Mus. Nat. Hist., Misc. Publ. No. 52: p161) reports an average litter size of 16.0 from 20 litters recorded for the species *N. erythrogaster*. They ranged in numbers from 5 to 27. A litter size of 28 is apparently the maximum recorded for this species.

Submitted by **DONALD D. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th St. and Rainbow Blvd., Kansas City, Kansas 66103, U.S.A. ●

NERODIA SIPEDON SIPEDON (Northern Water Snake). **REPRODUCTION.** Ectopic pregnancy, in which the embryo develops outside of the normal reproductive tract, has been reported for a number of vertebrates including humans, non-human primates and a variety of domestic animals (Benirschke, Garner and Jones. 1978. Pathology of Laboratory Animals, Vol. 1. Springer-Verlag, New York). Because normal parturition is not possible, such embryos may be retained intro-abdominally.

Retention of eggs by *Lissemys punctata punctata* has been reported by Duda and Gupta (1978. Intra-abdominal retention of eggs by the soft-shelled turtle *Lissemys punctata punctata*. SSAR Herp. Review 9(2): 46), and Hoffman (1970. Observations on gestation in the garter snake, *Thamnophis sirtalis sirtalis*. Copeia 4:779-780) reported several instances of extra-uterine embryos in the coelomic cavity of the Eastern garter snake. This paper is the first report of an ectopic pregnancy in another well-studied viviparous natricine genus, *Nerodia*.

As part of a study on the home range and movement of *Nerodia sipedon sipedon* at the Thunderbird Recreation Area (Walworth County, Wisconsin), a female *N. s. sipedon* (750 mm SVL, 390 g) was captured by hand 28 June 1982. Dried blood on the lower labial, upper labial and ocular scales suggested that the snake had been traumatized some period prior to capture. The snake was retained for routine processing and died soon thereafter. A necropsy was performed (UF 53664, UF 53665).

The snake was gravid, with 20 embryos in the right uterine horn and seven embryos in the left uterine horn. In addition, three fully developed extra-uterine fetuses were found at the extreme caudal end of the coelomic cavity. The embryos were coiled inside translucent membranes (presumably the chorion, the allantois and the shell membrane) and joined serially to one another. Coagulated blood surrounded the fetuses. Adjacent to this region, on the right side, there was a separation of ribs and a triangular gap in the costal musculature. The fetuses were intact but compressed and semi-mummified. Their integument was caseated and slightly discolored.

Since normal parturition for this subspecies usually occurs in late August or early September, it is probable that there was retention of the fetuses for approximately 10 months. There was no indication of active resorption or encapsulation of the fetuses or their membranes.

Despite the lack of detailed histopathology, the degenerating fetuses may have contributed to the death of this animal. Indications of trauma mentioned earlier and the close proximity of a service road to the collection site suggest possible external causes of death.

I would like to extend a special thanks to Dr. R. A. McCabe and Dr. E. R. Jacobson for their help with this note, and to the Wilkie Bros. Foundation for its support.

Submitted by **HARRY M. TIEBOUT, III,** Department of Zoology, University of Florida, Gainesville, Florida 32611, U.S.A. ●

PYTHON MOLURUS BIVITTATUS (Burmese Python). **MORPHOLOGY.** While two-headed snakes are well known (Frye, 1981. Biomedical and Surgical Aspects of Captive Reptile Husbandry, Chapter 13), few instances are documented of two-headed large constrictors or this anomaly occurring in captively reproduced serpents.

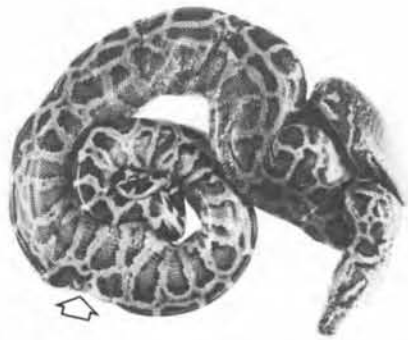

Figure 1. Dorsal view of two-headed Burmese python embryo. Note the ectopic location of ventral scalation (arrow).

Figure 2. Ventral view of two-headed Burmese python embryo.

Figure 3. Radiograph of two-headed Burmese python embryo.

On 12 June 1981 a full term derodymus embryo was found dead in the egg of a captive bred, maternally incubated clutch of Burmese python eggs. The egg failed to hatch and was slit by the authors after palpation revealed internal movement. Upon later return, no movement was noted and a dead embryo was extracted. It measured 58 cm in total length with cervical union occurring 9 cm below the base of the skulls. A small patch of ventral scales was apparent on the dorsal surface at the level of the umbilicus. Interestingly, another egg in this same clutch yielded twins.

Submitted by **BOB CLARK,** 8100 North Classen, Suite 101, Oklahoma City, Oklahoma 73114 and **TIM TYTLE,** Department of Radiological Sciences, Oklahoma Memorial Hospital, P.O. Box 26307, Oklahoma City, Oklahoma 73126, U.S.A. ●

SONORA SEMIANNULATA (Groundsnake) **COLORATION.** *S. semiannulata* is highly polymorphic in color; consequently, a plethora of pattern descriptions have been reported. The most thorough descriptions for the entire species complex were presented by Wright and Wright (1957. Handbook of Snakes of the United States and Canada. ix + 1105 pp.). In addition, Echternacht (1964. Herpetologica 20:211-212) reported an albino.

A melanistic *Sonora* was captured in Taney County, Missouri on 21 May 1981. The majority of cephalic and dorsal scales were thoroughly and densely pigmented giving the individual an overall glossy black appearance. The supra- and infralabials, chin shields and mental were lightly stippled with black pigment as were a few dorsal scales. Light stippling of black pigment occurred on the ventrals and subcaudals giving the entire venter a dusty appearance. The iris and tongue were black.

The specimen (UMC 562 S) is an adult female with a total length of 272 mm and a snout-vent length of 228 mm. Scutellation includes 156 ventrals, 40 subcaudals, scale rows 17-15-15, preoculars 1-1, postoculars 2-2, temporals 1-2 on both sides, supralabials 7-7, infralabials 7-6; the loreal is present and the anal is divided.

Columbia, Missouri. Present Address: Department of Zoology, Washington State University, Pullman, Washington 99164-4220, U.S.A. ●

TESTUDINES

CLEMMYS MUHLENBERGI (Bog Turtle). **REPRODUCTION.** Behler and King (1979. The Audubon Field Guide to North American Reptiles and Amphibians. Alfred A. Knopf, N.Y. p. 456.) list the range for single clutch size in *Clemmys muhlenbergi* as 1-6 eggs and Ryan (1981. Bull. Maryland Herp. Soc. 17(3): 102-6) reported six eggs from a record sized (105.8 mm) female *C. muhlenbergi* from Pennsylvania.

An adult pair of *C. muhlenbergi* obtained by the AZP 12 May 1967 has produced fertile eggs for nine consecutive years (Herman, D. W. 1980. Animal Keeper's Forum. AAZK. 7(19):198). No more than three eggs per clutch was recorded during this period. On 8 June 1983, six eggs were found deposited at a depth of 49 mm in a *Sphagnum* moss mound in a naturally planted bog used to house the adults. No measurements were recorded as the eggs were left in the nest for incubation. A dial thermometer (° C) was placed in the nest cavity to record the daily range in temperature of the eggs. The nest temperature recorded during incubation ranged from 24-32° C although the ambient temperature for the Atlanta area ranged between 20-37° C.

The six eggs hatched between 1 August and 3 August 1983 after 54-56 days. The neonates were weighed and measured within 48 hours of emerging from the eggs. A triple beam balance and vernier calipers were used to record the following data from the six neonates.

Carapace Length (mm)	24.5-26.4	$\bar{x}$= 25.4
Carapace Width	19.5-21.0	$\bar{x}$= 20.2
Plastron Length	19.4-21.4	$\bar{x}$= 20.4
Plastron Width	11.0-12.6	$\bar{x}$= 12.0
Shell Height	12.3-13.2	$\bar{x}$= 12.8
Weight (g)	3.52-4.50	$\bar{x}$= 4.00

The neonates are being housed in a 10 gal aquarium with *Sphagnum* moss substrata and a 25 mm water depth to prevent drowning. Chopped minnows and earthworms, calcium dusted crickets, and Frog Brittle ® (NASCO, Fort Atkinson, WI) make up the diet. UV is provided four min daily with a 275 W sunlamp with timer.

The six eggs reported herein equals the maximum single egg clutch for *Clemmys muhlenbergi* and the six live neonates betters by one the previous high for the species (Ryan, op. cit.).

Submitted by **DENNIS W. HERMAN,** Department of Herpetology, Atlanta Zoological Park, 800 Cherokee Ave. SE, Atlanta, Georgia 30315, U.S.A. ●

TRIONYX FEROX (Florida Softshell). **REPRODUCTION.** The production of more than one clutch of eggs annually by *T. ferox* has been presumed, but not reported as a result of direct observation. A female (carapace length 41 cm) was donated to the Columbus Zoo 3 November 1973. The specimen was noted to have been collected in Ware County, Georgia in June 1973, and to have laid an indeterminate number of eggs while in the possession of the donor. An additional four eggs were laid 4 November 1973. The female was subsequently housed with an exceptionally large male (carapace length 37 cm) which had been received by the zoo 26 July 1962.

The female laid a clutch of 24 eggs on 19 July 1979, eight of which were large, yellow and presumably infertile. The infertile eggs ranged from 31 to 33 mm ($\bar{x}$=32.3 mm) along the long axis and from 29 to 31 mm ($\bar{x}$=29.8 mm) along the short axis. The 16 normal eggs ranged from 29 to 33 mm ($\bar{x}$=30.7 mm) along the long axis and from 28 to 31 mm ($\bar{x}$=29.1 mm) along the short axis. Fifteen of these eggs hatched between 27 August and 15 September 1979, after 39 to 58 days incubation at approximately 30° C.

A second clutch of 13 eggs was laid 1 August 1979, which included no infertile eggs, but one which was cracked during laying and is excluded from the data. The twelve eggs ranged from 28 to 31 mm ($\bar{x}$=30.0 mm) along the long axis and from 27 to 31 mm ($\bar{x}$=29.0 mm) along the short axis. Eleven of these hatched between 4 and 8 October 1979, after 64-68 days incubation. The 26 hatchlings from both clutches had carapace lengths of 47-51 mm within five days of hatching, and no apparent difference occurred in size between the two clutches.

The age of the male is further noteworthy. Assuming copulation to have occurred in spring or early summer of 1979, at the time of insemination the male had been in the collection for a time near or exceeding the published longevity record for the form (Bowler. 1977, SSAR Herp. Circ., 6). As the animal was noted to have been "large" at the time of accession, the actual age of the animal at the time of copulation may have well exceeded twenty years.

Submitted by **MIKE GOODE,** Columbus Zoo, Columbus, Ohio 43065, U.S.A. ●

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

ANURA

PSEUDACRIS TRISERIATA (Chorus Frog). USA: MINNESOTA: Wabasha Co: McCarthy Lake Wildlife Management Area west of County 84 (T-109N, R-10W, Sec. 1). 8 July 1983. Philip A. Cochran with Joseph A. Cochran. University of Wisconsin-Madison, Zoological Museum (UWZH 22557). One of three individuals discovered beneath sections of logs in a sandy prairie area, the only damp substrate for 100-200 m from possible breeding areas in an intermittent tributary of the Old Channel of the Zumbro River and a nearby pond. First published record for Wabasha Co (Breckenridge, 1944, Reptiles and Amphibians of Minnesota. Univ. Minnesota Press; Minnesota Dept. of Natural Resources, 1979, Guide to the Reptiles and Amphibians of Southeast Minnesota - Region 5).

Submitted by **PHILIP A. COCHRAN,** Center for Limnology, University of Wisconsin, Madison, Wisconsin 53706, U.S.A. ●

TESTUDINES

CHRYSEMYS PICTA (Painted Turtle). USA: MINNESOTA: Wabasha Co: County 84 south of McCarthy Lake Wildlife Management Area (T-109N, R-8W, Sec. 7). 8 July 1983. Philip A. Cochran with Joseph A. Cochran. University of Wisconsin-Madison, Zoological Museum (UWZH 22558). Road-killed adult, probably originating from a pond visible 100-200 m to the west. First published record for Wabasha Co (Breckenridge, 1944, Reptiles and Amphibians of Minnesota. Univ. Minnesota Press; Ernst, 1973, J. Herpetology 7:42-47; Minnesota Dept. of Natural Resources, 1979, Guide to the Reptiles and Amphibians of Southeast Minnesota - Region 5), but many specimens

were also collected and observed during the course of fieldwork in 1975 and 1976 in Half Moon Lake and the Weaver Bottoms, nearby backwaters of the Upper Mississippi River.

Submitted by **PHILIP A. COCHRAN,** Center for Limnology, University of Wisconsin, Madison, Wisconsin 53706, U.S.A. ●

CLEMMYS GUTTATA (Spotted Turtle). USA: FLORIDA: St. Johns Co: Trestle Bay Swamp, 8.4 km E SR13A on C214, R29E, T7S, Sec. 29. 23 March 1982. Tim Williams. Verified by K. A. Vliet. Univ. Florida, Florida State Museum (UF 52599). Adult female. Putnam Co: behind Army Corps of Engineers, R26E, T10S, Sec. 2. March 1982. Frank Brandt. Verified by P. A. Meylan. (UF 52600). Adult male. Specimens extend known range of species ca. 25.4 km SSE in St. Johns County and ca. 12.25 km NE in Putnam County from previously reported specimens (Banicki, 1981, Florida Sci. 44(4): 253-254).

SAURIA

CNEMIDOPHORUS TIGRIS (Western Whiptail). CALIFORNIA: Santa Clara Co: ca. 3-4 miles SE of Los Gatos (Limekiln Canyon, alt. ca. 2000 ft., Soda Springs Canyon, alt. ca. 1600 ft.); 1½ miles SW of New Almaden (Hicks Road, alt. ca. 700 ft.); ca. 9 miles S of Palo Alto (SW flank of Black Mountain, alt. ca. 2800 ft.). Verified from photograph (see Figure 1) by Robert Stebbins. All were along chaparral margins. The Los Gatos, New Almaden and Black Mountain populations were under, respectively, *Baccharis pilularis consanguinea, Artemisia californica* and *Ceanothus cuneatus.*

These 1981, 1982 and 1983 sightings in the Santa Cruz Mountains extend the known range of this polytypic southwestern species about 30 miles westward from the inner Coast Range locations given by Stebbins (1954). I saw only 1 to 3 individuals at each site, and only in the period from late May to early July. The species seems to be uncommon here. I have botanized all but the Black Mountain area repeatedly since 1965 without seeing *C. tigris,* and other naturalists in this densely populated region appear to have missed it also. It seems to prefer open shade where the

ubiquitous Western Fence Lizard *(Sceloporus occidentalis)* is absent or uncommon.

Submitted by **JOHN S. MOORING,** Biology Department, University of Santa Clara, Santa Clara, California 95053, U.S.A. ●

OPHISAURUS ATTENUATUS ATTENUATUS (Western Slender Glass Lizard). USA: MISSOURI: Wayne Co: Specimen DOR on St. Rt. 143, 1.0 km south entrance to Sam A. Baker State Park. 29 May 1976. Collected by M. J. Lodato and P. J. Lodato. Verified by Dennis Harris, University of Michigan Museum of Zoology (UMMZ 174765). First record for Wayne County and extends Missouri range ca. 100 km southeast from nearest published locality (Anderson, 1965 *Reptiles of Missouri,* Univ. Missouri Press, and Holman, 1971, *Ophisaurus attenuatus,* Cat. American Amphib. Rept.).

PHRYNOSOMA DITMARSI (Rock Horned Lizard). MEXICO: SONORA: ca. 23 km (airline) SE Highway 16 bridge over the Río Yaqui near Tonichí (ca. 165 km (airline) SE Hermosillo, Sonora at an elevation of approximately 1050 m. Collected at approximately 1400 hrs. on 14 March 1983 by Robert H. Perrill. A first-year subadult (5 cm TL) was photographed by the author, but lacking a Mexican scientific collecting permit, the specimen was not collected. The species identification was verified by Charles H. Lowe from photographs which were accessioned to the University of Arizona's herpetological photo specimen voucher file (UAZ 44950 PSV). For the first time *Phrynosoma ditmarsi* has been found in the Río Yaqui drainage system in southeast central Sonora. The only previously recorded collection sites of *P. ditmarsi* have been in the Río Sonora drainage of northeastern Sonora (Lowe, C. H., M. D. Robinson and V. D. Roth, 1971, J. Ariz. Acad. Sci. 6:275-277; Lowe, C. H. and C. W. Howard, 1975, Southwest. Nat. 20:265-270). The lizard was found on a steep, south-facing slope with widely scattered rocky outcrops. It moved from the partial shade of *Fouquieria macdougalli* (Mexican tree ocotillo) and was caught on a fallen branch of *Ceiba acuminata* (Kapok). The habitat was in short-tree forest (Gentry, 1942, Rio Mayo Plants, Carnegie Institute of Washington Publication 527) secondly Sinaloan Deciduous Forest (Brown, D. E., C. H. Lowe and C. P. Pase, 1980, A Digitized Systematic Classification for Ecosystems with an Illustrated Summary of the Natural Vegetation of North America, USDA Forest Service, Rocky Mtn. Forest and Range Exp. Sta., Gen. Tech. Rep. RM-73:1-93) with *Acacia cochliocantha* (boatspine acacia), *Lysiloma watsonii* (feather tree), *Bursera fagaroides elongata* (elephant tree) and *Ipomoea arborescens* (tree morning glory) among the dominant plant species. Except for a few scattered oaks *(Quercus albocincta* and *Q. chihuahuensis)* this locality is quite different from the other known habitats of *P. ditmarsi* which are primarily open oak or oak-pine woodlands with two dominant oak species, some shrubs, and many perennial grasses (op. cit.) This report establishes the occurrence of *P. ditmarsi* in a second river drainage and an unrecorded plant community, as well as extending the range by ca. 150 airline kilometers south-southeast from the nearest previously recorded locality.

SERPENTES

COLUBER CONSTRICTOR (Racer). USA: WISCONSIN: Crawford Co: State Highway 179, about 1/3 km east of the Kickapoo River (T-8N, R-4W, Sec. 7/8). 29 July 1983. Philip A. Cochran with John D. Lyons. University of Wisconsin-Madison, Zoological Museum (UWZH 22560). Road-killed adult, found where road cuts along north side of wooded bluff, with immediate roadsides vegetated by grasses and brush. First published record for Crawford Co (Vogt, R. C. 1981. Natural history of amphibians and reptiles of Wisconsin: Milwaukee Public Museum, Milwaukee, 205 pp.).

Submitted by **PHILIP A. COCHRAN,** Center for Limnology, University of Wisconsin, Madison, Wisconsin 53706, U.S.A. ●

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). USA: UTAH: Uintah Co: 2 mi. N Jones Hole Campground, along Green R. 27 July 1982. G. H. Clemmer. U.S. Biological Survey collection/Fort Collins, CO (BS/FC 02000). The new record is just west of the Utah-Colorado border and is the northernmost record of isolated populations west of the continental divide (Conant, R. 1975. A Field Guide to Reptiles and Amphibians). This specimen extends the range of the species about 100 km NE of the nearest Utah locality "about 15 miles down river from Ouray, Unita County" (Stebbins, R. C. 1954. Amphibians and Reptiles of Western North America), and about 160 km NW of three localities in eastern Garfield County, Colorado (Hammerson, G. A. 1982. Amphibians and Reptiles in Colorado. Colo. Div. Wildlife, DOW-M-I-27-82. 130 pp.).

Submitted by **R. BRUCE BURY,** Denver Wildlife Research Center, 1300 Blue Spruce Drive, Fort Collins, Colorado 80524, U.S.A. ●

LEPTOTYPHLOPS DULCIS DISSECTUS (New Mexico Blind Snake). USA: COLORADO: Baca Co: 39.5 km S, 3 km E Pritchett, Sand Canyon (E½ SW¼ NW¼ Sec. 9, T35S R48W). 1317 m. 11 June 1983. 12:00-13:00 MDT. Three live specimens collected and

identified by D. Jaggi, M. Cage, M. C. Mulvany, P. S. Mulvany, R. Guese, Y. Cage and S. Sasman. Verified by Geoffrey A. Hammerson. University of Colorado Museum, Boulder (UCM 55594-55596). Found under sandstone rocks on steep SW-facing slopes below cliffs. These specimens corroborate the state record for this species which is based on a shed skin (Lapin, B. P. and G. A. Hammerson. 1982. Geographic distribution: *Leptotyphlops dulcis*. SSAR Herp. Review 13(3):82). The new locality is 19.5 km E, 2.5 km S of the state record locality.

Submitted by **DAVE JAGGI, MATT CAGE, MARK C. MULVANY, RAY GUESE, YOUNG CAGE and STEVE SASMAN,** Colorado Herpetological Society, P.O. Box 15381, Denver, Colorado 80215, and **PATRICK S. MULVANY,** Oklahoma Herpetological Society, 7315 East 81st Place, Tulsa, Oklahoma 74133, U.S.A. ●

NERODIA SIPEDON (Northern Watersnake). USA: WISCONSIN: Green Co: Sugar River, immediately downstream from Ten Eyke Road bridge crossing (T-2N, R-9E, Sec. 35). 16 June 1983. P. A. Cochran with J. D. Lyons and F. J. Rahel. University of Wisconsin-Madison, Zoological Museum (UWZH 22559). At least two other individuals were sighted. First published record for Green Co (Vogt, R. C. 1981. Natural history of amphibians and reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee, 205 pp.). This probably reflects a lack of collecting effort, as not even the ubiquitous *Chelydra serpentina* or *Chrysemys picta* have been recorded from Green Co (Vogt, op. cit.). We collected and released a specimen of the former at this site on the same day as the watersnake.

Submitted by **PHILIP A. COCHRAN,** Center for Limnology, University of Wisconsin, Madison, Wisconsin 53706. ●

FIRST SPECIMEN OF *Ambystoma tremblayi* FOR ALGONQUIN PARK, ONTARIO

The presence of Tremblay's salamander *(Ambystoma tremblayi)* has been documented for a number of locations in southern Ontario (Uzzel, 1964; Weller, Sprules, and Lamarre, 1978; Weller *et al.*, 1979). The northernmost record for the province is that of a single individual captured in Algonquin Provincial Park in 1974 (Brunton and Weller, 1979). This record was based solely on the length and coloration of an animal that was not preserved. Considering the great difficulty of distinguishing Ontario members of the *A. jeffersonianum* complex from morphology alone (Servage, 1979), it was desirable to confirm the occurrence of *A. tremblayi* in this area.

A large salamander of the *A. jeffersonianum* complex was captured by J. Murphy at the Algonquin Park Museum (45° 33'N 78 38'W) early in the summer of 1981. It was sent to the University of Guelph for determination. In this complex the ploidy can be determined by chromosome counts (Servage, 1979) or by erythrocyte measurements (Austin and Bogart, 1982). Triploid specimens can be referred to *A. tremblayi* by examining the pattern of electrophoretic separation of glutamate oxaloacetic transaminase, malate dehydrogenase, and superoxide dismutase isozymes (Servage, 1979; Bogart, *in press*). Chromosome counts from the Algonquin Park specimen, using Kezer and Sessions (1979) technique as modified by Servage (1979), indicated that is was a triploid (3n=42). The electrophoretic patterns of malate dehydrogenase isozymes confirmed that it was *A. tremblayi*. The specimen is deposited in the herpetological collection of the Royal Ontario Museum (ROM 11052).

The Algonquin Park Museum is located approximately 4 km E of the site of the previous Algonquin record. It is situated at an elevation of 472 m and is surrounded by mixed forests of Sugar Maple *(Acer saccharum)*, Yellow Birch *(Betula alleghaniensis)*, Beech *(Fagus grandifolia)*, spruces *(Picea* spp.), Balsam Fir *(Abies balsamea)*, and other species. Blue-spotted salamanders *(A. laterale)* were also identified from this location on the basis of electrophoretic patterns and chromosome counts. The Algonquin records extend the known range of *A. tremblayi* by approximately 50 km to the northeast.

I would like to thank J. P. Bogart for assistance in the lab and for reviewing this manuscript; thanks also to the staff of the Algonquin Park Museum.

THE STATUS OF *Clemmys muhlenbergii* (SCHOEPFF) IN CONNECTICUT

Several authors have mentioned the probable occurrence of *Clemmys muhlenbergii* in Connecticut, including Babcock (1919), Lamson (1935), and Barton and Price (1955). Warner's (1975) records from western Connecticut are unsubstantiated by specimens. Ernst and Bury (1977) and Bury (1979) map Connecticut localities that Nemuras (1975) based on "reports from reliable individuals," literature reports, and one voucher specimen. The only adequately documented locality in Connecticut for this species is Roxbury, Litchfield County (Robinson, 1956), and the voucher specimen (YPM 2215) cannot now be found in the Yale University collection (F. Sibley, pers. comm.).

Recent intensive field work by the authors and William Zovickian has resulted in documentation with museum specimens and/or photographs of *C. muhlenbergii* from the following localities: FAIRFIELD CO: Bethel (photograph); Ridgefield (AMNH 119267-69); LITCHFIELD CO: Salisbury (UCS 5795, 7156-57, 7382); Sharon (AMNH 120255, UCS 7138, photographs). Bog turtles were not sacrificed to document localities. Road killed individuals, empty shells and, in two instances, individuals that died in captivity were utilized. The collection sites are in or near the calcareous valley system of extreme western Connecticut. A positive distribution correlation between *C. muhlenbergii* and calcareous wetlands in the State was suggested by Dowhan and Craig (1976).

Current rapid development in upper Fairfield County (Danbury and Ridgefield) has severely affected or destroyed populations of this species by filling, damming, and channeling of wetlands. Many species of turtles are killed on roads that dissect the wetlands, including an occasional *C. muhlenbergii*.

Without some measure of habitat protection, *C. muhlenbergii* could be extirpated from Connecticut in the near future. The State of Connecticut and conservation organizations should implement a vigorous program to locate viable populations of bog turtles. Measures must be taken to safeguard the immediate habitat and external factors which might influence the quality of the habitat, such as water supply. In some areas, management of habitats to favor bog turtles will be warranted. Calcareous wetlands comprise a small portion of the total area of the State and support a unique floral and faunal assemblage. Protection of these habitats

would enhance other rare species' survival. Detailed studies concerning the life history and ecology of this species at its northeastern range limit should be undertaken and compared to studies done in the more central and southern portions of its range.

ACKNOWLEDGMENTS

We acknowledge access to the collections of the American Museum of Natural History (AMNH), University of Connecticut, Museum of Natural History (UCS), and Yale University Peabody Museum (YPM). For generously sharing information with us we are grateful to W. Zovickian, L. Whitham, and E. Briggs. Field work was conducted under a scientific collector's permit issued to MWK by the State of Connecticut, Department of Environmental Protection. MWK acknowledges support from The Nature Conservancy, Connecticut Chapter.

UPDATE ON THE LIST OF AMPHIBIANS AND REPTILES KNOWN FROM HONDURAS

Twelve years have passed since the Honduran amphibian checklist appeared (Meyer and Wilson, 1971). The lizard, turtle, and crocodilian checklist was published ten years ago (Meyer and Wilson, 1973); the work on the snakes of Honduras has just appeared (Wilson and Meyer, 1982). Field work has continued throughout this time and a number of species have been added to the country's herpetofauna or described as new from the country, bringing the total to 208. As such, the time is ripe for producing a summary list of the amphibians and reptiles now known to occur in Honduras.

The species are listed in alphabetical order under each order. Each name is followed by a number in parentheses which refers to a numbered reference in the Literature Cited section in which that species was reported for Honduras.

ORDER GYMNOPHIONA (2 species)
Dermophis mexicanus (6)
Gymnopis multiplicata (6)
ORDER CAUDATA (11 species)
Bolitoglossa dofleini (6)
Bolitoglossa dunni (6)
Bolitoglossa mexicana (6)
Bolitoglossa occidentalis (6)
Bolitoglossa rufescens (6)
Bolitoglossa schmidti (6)
Bolitoglossa striatula (6)
Chiropterotriton barbouri (6)
Chiropterotriton nasalis (6)
Oedipina cyclocauda (6)
Oedipina stuarti (6)
ORDER ANURA (43 species)
Agalychnis callidryas (6)
Agalychnis moreleti (6)
Bufo cavifrons (6)
Bufo coccifer (6)
Bufo haematiticus (2)
Bufo leutkeni (6)
Bufo marinus (6)
Bufo valliceps (6)
Centrolenella fleischmanni (6)
Eleutherodactylus biporcatus (6)
Eleutherodactylus bransfordi (8)
Eleutherodactylus gollmeri (6)
Eleutherodactylus laticeps (6)
Eleutherodactylus merendonensis (6)
Eleutherodactylus milesi (6)
Eleutherodactylus mimus (6)
Eleutherodactylus noblei (6)
Eleutherodactylus ridens (6)
Eleutherodactylus rugulosus (6)
Gastrophryne elegans (6)
Hyla bromeliacea (6)
Hyla loquax (6)
Hyla microcephala (6)
Hyla picta (6)
Hyla salvadorensis (6)
Hyla staufferi (6)
Hypopachus variolosus (6)
Leptodactylus fragilis (as *L. labialis*) (6)
Leptodactylus melanonotus (6)
Leptodactylus pentadactylus (6)
Leptodactylus silvanimbus (5)
Phrynohyas venulosa (6)

BOOK REVIEWS

Japan's Schlangen (Volume 1), by Max Mori. 1982. Igaku-Schoin, Ltd., Tokoyo. 80 pp. ¥ 10,000. (approximately $42.00).

This slim book is the first volume of a projected three-volume review of the snakes of Japan, including the Riukiu Archipelago and islands of the Yaeyama group. According to the author's foreword the completed work will be a color atlas of Japanese snakes, and also a guide for "quick, simple, and correct diagnosis" of the species covered. In my opinion, this first volume falls far short of both goals.

The species accounts (given in both Japanese and German) include information under the following general headings: classification, size, diagnostic characteristics, color, venom, and distribution. The style throughout is stilted and pedantic, and the content is not particularly informative. The sections on diagnostic characters are especially discursive and poorly organized. In comparison with the terse, highly functional diagnoses of modern field guides, these rambling descriptions seem hardly "diagnostic." Although they may accomplish the author's stated goal of correct diagnosis, they could not be expected to work either quickly or simply.

A large portion of the volume (19 pages) is occupied by the color photographs, which for the most part are embarrassingly bad. Seven species are covered: *Rhabdophis tigrinus, Opheodrys semicarinatus, Amphiesma pryeri, Agkistrodon blomhoffi, Trimeresurus okinavensis, Trimeresurus flavoviridis,* and *Elaphe climacophora.* Color variants of *Rhabdophis tigrinus* and *Trimeresurus flavoviridis,* and a juvenile *Elaphe climacophora,* are thrown in for good measure.

For each species or variant a suite of three to nine photos, all of a single individual, is presented. The photographs are of living snakes, some of them showing the wear and tear of unhappy captivity. The pictures include full-body photos, and closeups from top, bottom and side of the head, midbody, and anal region or tail. There is no apparent uniformity to the style or scale of photographs presented for each species. Some of the photos were posed with the aid of fingers, which also figure prominently in the pictures, and for others the snakes were apparently anesthetized. The backgrounds are a variety of terrarium bottoms and table cloths.

Even conceding the difficulty of obtaining high-quality portraits of living, wriggling subjects (admittedly Isabelle Hunt Conant set a very high standard for such endeavours), there is no excuse for publishing photographs that are not sharply focused. Not only are many of the photographs fuzzy, but the color renditions are of extremely variable quality. I found it curious to encounter both poor photographic technique and inferior color printing in a book produced in Japan, a country that typically leads in both technologies.

It is customary to write, toward the end of an unfavorable review, "this book has little to recommend it." In this case, however, the book has nothing to recommend it, not even a reasonable price.

Dinosaurs, Asteroids and Superstars: Why the Dinosaurs Disappeared, by Franklyn M. Branley with illustrations by Jean Zallinger. 84 pp. 1982. Thomas Y. Crowell Junior Books (NY). $9.50 ISBN 0-690-04211-6.

While I don't expect that *HR* will be deluged with reviews of books for youngsters, it's certainly not inappropriate that we review some since the herpetological interests of many of us extend to childhood and the progeny of herpetologists sometimes share said interests.

This is a fine book, both in content and form. It will, I feel, appeal most to youngsters between 8 and 14 years old. The text is well designed with easily read fonts and adequate line leading. The general readability and appearance of the book are further enhanced by the use of a good glossy paper. Ms. Zallinger's drawings are skillful, simple and interesting, and are nicely employed to break up passages of text. The book shows evidence of careful editing, and I did not notice any typographical or grammatical errors. The index is adequate, and a small list of further reading suggestions is provided.

The author gives very good and relatively unbiased accounts of contemporary theories regarding the great extinctions of the late Cretaceous. The major historical theories are also reviewed and evidence contradicting them is concisely presented. I found very little material to quibble over. On page 18, the author writes that "Dinosaurs were indifferent mothers." Evidence accumulated for crocodilians in the past few years documenting rather intense maternal care makes that generalization less acceptable for late Cretaceous Archosauria than it was considered 8 years ago. Similarly, I feel that the implication that the decreasing thickness of eggshells seen through the Cretaceous is a sign of reproductive decline (page 20) is somewhat premature. Paleontologists really do not know that much about the evolution of egg structure in dinosaurs, and assigning most nests accurately to genus would be an awesome accomplishment. Contemporary reptile eggs are not very thick walled.

These are really minor flaws. The author concludes with the fact that all young readers of active imagination and curiosity will find so intriguing: we do not know why the spectacular age of the great reptiles came to so precipitous a conclusion. In the long run, it is this same intrigue that most scientists find so fascinating in their professions.

Lizards of Western Australia I. Skinks, by G. M. Storr, L. A. Smith, and R. E. Johnstone. University of Western Australia Press, 1981. 200p ill. $23.00. Obtainable from International Scholarly Book Services, PO Box 1632, Beaverton, Oregon 97075.

This is the first in the series of a projected 3-volume handbook on the lizards of Western Australia. The dragon lizards, monitors and geckos will appear in later volumes. Australia is blessed with a plethora of skinks; there are 15 genera and 130 species in western Australia alone and the purpose of this handbook is to make it possible for any interested person to identify each species. There are keys to the genera and to the species and there is a brief diagnostic description of each species, a map showing the distribution within the western portion of Australia only, and oftimes an illustration of the head scalation. It is good to have such an excellent guide to this remarkable diversity of lizards especially when the senior author alone is responsible for the description of nearly half of the species listed. Study on the comparative ecology and behavior of these many closely related forms should be enhanced by the availability of this publica-

tion. The center contains 20 color plates, each with 6 or 8 excellent color photographs of the individual species and at the end there is a glossary and a bibliography. An excellent contribution.

A Guide to Field Identification - Reptiles of North America, by Hobart M. Smith and Edmund D. Brodie, Jr. Golden Press (Western Publishing Company, Inc., Racine, Wisconsin), 240 pp., 1982. $6.95.

My immediate reaction upon seeing this book was: "What?! Yet another field guide to the herps of North America?" After all, in recent years (since 1966) we have witnessed the appearance of four other field guides in three series, However, in the course of preparing this review, my opinion of Smith and Brodie's book changed considerably. This book is a companion volume to *A Guide to Field Identification - Amphibians of North America* (1978) by Dr. Smith and both are part of the Golden Field Guide Series. Both authors are well-known herpetologists; Dr. Smith is one of a very few "deans of American herpetology."

This field guide is directed toward an audience of lay people and amateur herpetologists but it can also be useful to professional herpetologists as a convenient source of information concerning North American reptiles (north of Mexico) occurring outside of the area of their immediate expertise.

The book is organized into three main sections, viz.: (1) an introduction to the group discussed and to the use of the book, as well as basic information on snakebite and treatment; (2) an identification guide to North American species; (3) basic information about reptilian biology and maintenance of reptiles in captivity. The information in the first section is written to be intelligible to any literate adult, with technical terminology minimized and otherwise explained. Sections on ethics and the growing value of observation vs. "collecting" are especially important. The coverage of snakebite and treatment is simplified but emphasizes remaining calm and movement of the victim to a medical facility without delay.

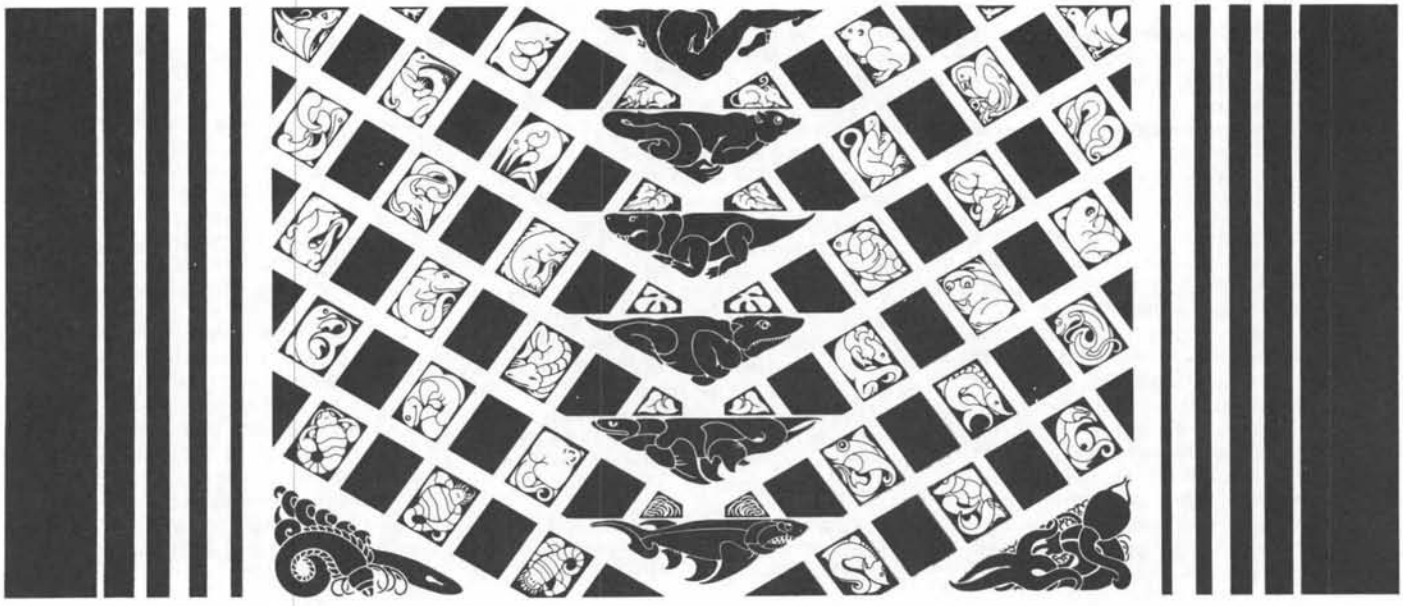
The section on identification is set up in a very useful fashion. The infrataxa within each major reptile group are discussed in a decreasing hierarchical order. At each level, general introductory remarks are provided and, for the purposes of identification: (1) illustrations of key characteristics and the animals themselves; (2) range maps; (3) species and subspecies descriptions; and (4) keys (this is the order the authors suggest for their use in identification). The illustrations are line drawings and paintings and are, simply speaking, superb. They were executed by David Dennis and Sy Barlowe and represent the outstanding feature of this book. Mr. Dennis is a major talent in the world of herpetological illustration. The line drawings are intended as visual explanations of the characters used in the keys and use a pale yellowish green color as a visual key to highlight the field marks (analagous to the Peterson series "arrows"). The paintings of the various species are of uniformly high quality, although the definition of some is better than in others. The only fair comparison of these paintings is with those in Stebbins' 1966 *Field Guide to Western Reptiles and Amphibians.* Comparing species by species, Dr. Stebbins' paintings exhibit an almost excruciating detail which is not matched by some of Mr. Dennis' work but this detracts in no serious way from their beauty and utility. The range maps are another matter. Although it is a definite plus to have these maps placed alongside their respective species accounts, some maps showing subspecies ranges are so small as to be practically useless (e.g., those of *Coluber constrictor, Holbrookia maculata,* and *Lampropeltis zonata*). The lack of state boundaries, impossible to use on maps which are smaller than the size of a postage stamp, further hinders their utility. Finally, precise overlap of some color components (to make orange, for example) is lacking, presenting confusion regarding subspecies range limitations in maps of such a small scale. The maps are, most assuredly, the weakest aspect of this book. The species and subspecies descriptions are precise and succinct. The keys are likewise and stress easily-observed features. Together, this quartet of identification guides, barring the weaknesses of the range maps, provides a facile method for determining identity, unequaled by those used in other recently-published field guides.

The final section on reptilian biology and care in captivity is written in a simple and pleasing fashion and is highlighted by a straightforward discussion of "the human factor" in destruction and endangerment of reptilian life.

At the beginning of this review, I expressed my initial sceptical attitude toward the publication of another North American field guide. In light of my own scepticism and perhaps that of others who will see the book, I think it useful to carry out a comparison of the recently-published field guides to reptiles and amphibians of North America north of Mexico or some segment thereof. In so doing, I constructed a chart (Table 1) that provides a comparison of salient features of such field guides, beginning with Robert C. Stebbins' 1966 field guide mentioned above. Of course, the more recently-published a field guide is, the more current it will be, but I feel there are other overriding features of field guides that may make an older field guide preferable for field use to a newer one, especially given the relative stability of our knowledge of the reptiles and amphibians north of the U.S.-Mexican border. I have tried to assess the relative utility of five recently-published guides by comparing them to what I consider to be "ideal" characteristics of such guides. An "ideal" field guide should have:

1. A descriptive title. Cochran and Goin's title "The new field guide of reptiles and amphibians" gives no indication of the area covered.
2. Reasonable cost. Even in the days of inflated book prices, Conant's and Stebbins' cloth-bound guides are comparatively expensive.
3. Professionally done illustrations (preferably paintings, line and stippled drawings, and line drawings, where pertinent; if not paintings, then excellent quality photographs in which the subject is positioned to show field identification marks) placed alongside the species accounts. Cochran and Goin's photographs do not even function well as portraits of the species in most cases.
4. Sufficiently larger and detailed distribution maps showing subspecies ranges and outlying populations or records, supplemented by sufficiently detailed written statements. As noted above, Smith and Brodie's maps are too small and confusing to be useful in many cases and Cochran and Goin's book contains no maps and has descriptions that are too poorly drawn in most cases to make up for the poor photographs. Behler and King's maps do not show subspecies ranges.
5. A variety of identification techniques, including at least visual keys, good illustrations, and sufficiently detailed written descriptions. Cochran and Goin's book is the worst of those compared herein in this regard.
6. Ancillary information on other aspects of the species' biology, as space permits. Conant's, Stebbins', and Smith and Brodie's guides are notable in this respect.
7. A glossary of pertinent technical terms. Cochran and Goin's is probably the most useful as it is more detailed and divided into sections that head each of the major group divisions of the book.
8. Size small enough to fit in a jacket pocket. All the guides correspond to this characteristic.

Based on these features, I tried to establish an overall rating for each of the guides listed in Table 1 between 0 and 8. Whereas no guide was an "ideal" one, the Smith and Brodie guide and the Stebbins one are the best of any of those considered, followed closely by Conant's. The Cochran and Goin and Behler and King guides never seem to have "caught on," perhaps with good reason, according to my rating, although the Cochran and Goin book is far the inferior of the two.



In the final analysis, Smith and Brodie's field guide, when combined with its sister volume on the amphibians, provides a valuable tool for field identification of North America's herpetozoans in a less bulky and only slightly less useful format than the Conant and Stebbins companion volumes. The book considerably enhances the growing reputation of Dr. Brodie (even though a reformed ophidiophobe) and adds another chapter to the history of Dr. Smith, one of the most remarkable men in herpetology.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

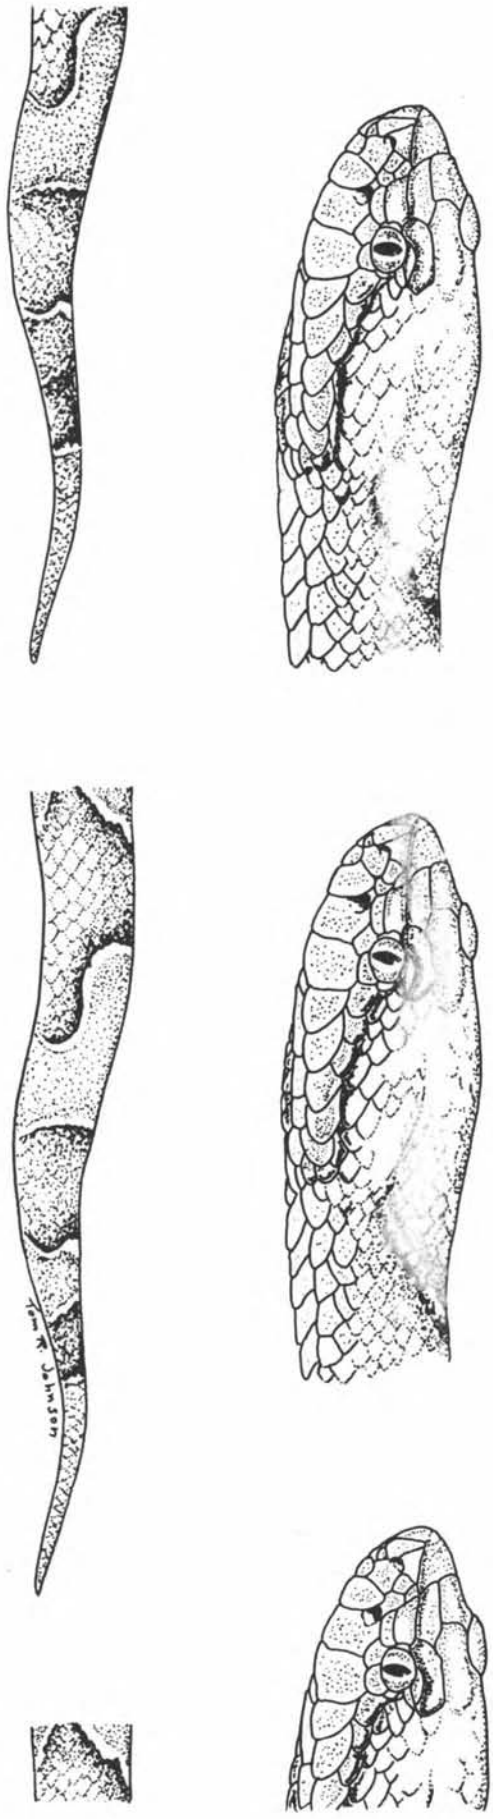
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1983

Student member	$15.00*
Regular member	$18.00*
Sustaining member	$30.00
Contributing member	$50.00
Institutional	$30.00*



***Non-U.S. members and institutions must also include $5.00 additional. This surcharge is to help defray higher mailing costs.**

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

1983 SSAR HERP CONSERVATION DIRECTORY AVAILABLE

The SSAR Conservation Committee has prepared a directory of state wildlife agency or commission employees who are responsible for nongame, significant habitat, or natural heritage programs. It includes the names of individuals who have been designated as contacts on issues concerning threats to herpetofaunal resources. The Committee hopes the "herp" conservation directory will serve as an aid to those needing to address amphibian and reptile conservation issues.

Copies are available, gratis, from: John L. Behler, Chairman, SSAR Conservation Committee, c/o Department of Herpetology, New York Zoological Society, 185th St. & Southern Blvd., Bronx, New York 10460 USA. ●

1983 SSAR GRANTS-IN-HERPETOLOGY AWARDS

The Society for the Study of Amphibians and Reptiles is pleased to announce the following awards in the 1983 Grants-in-Herpetology Program:

GRADUATE STUDENT RESEARCH:

Paul J. Watson, Section of Neurobiology and Behavior, Cornell University. "Chemical communication and sexual selection in the red-spotted newt, *Notophthalmus viridescens* (Rafinesque)." $450.

Robert A. Newman, Department of Biology, University of Pennsylvania. "The genetic basis of traits affecting larval survival of *Scaphiopus couchi*, a desert anuran (Pelobatidae)." $275.

Joyce S. Tsuji, Department of Zoology, University of Washington. "Latitudinal comparison of thermal acclimation of metabolism in lizards." $250.

REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS:

Kevin N. Brewster, Wisconsin Herpetological Society. "Reptilian ecology of endangered prairie habitat in Wisconsin." $250.

Steve Hammack, North Texas Herpetological Society. "A pictorial guide to the amphibians and reptiles of Dallas and Tarrant Counties, Texas." $200.

HERPETOLOGICAL CONSERVATION:

Peter W. Stangel, Department of Zoology, University of Georgia. "A proposed study of the breeding biology and larval ecology of the spotted salamander, *Ambystoma maculatum*." $400.

SSAR extends its congratulations to all recipients of awards and encourages the submission of proposals for next year's program. SSAR also expresses its thanks to the 1983 Grants-in-Herpetology Committee, composed of: Linda R. Maxson (Chairperson), Robert Mount (Conservation Research), Malvin L. Skaroff (Regional Herpetological Society Projects), Donald C. Forester (Graduate Student Research), and Dale L. Marcellini (Herpetological Research in Zoos). ●

SOCIETIES

CALIFORNIA CONFERENCE ON HUSBANDRY AND PROPAGATION

The Northern California Herpetological Society is hosting a conference on "Captive Propagation and Husbandry of Reptiles and Amphibians." The conference will take place on Saturday, 15 October 1983, and will consist of presentations by eight speakers. The keynote speakers will be Dr. Fredric Frye and Dr. Murray Fowler. Others on the agenda include Ron Tremper, Dr. Richard Ross, and Terry Lilley. For further information contact:

Northern California Herpetological Society
706 Arnold Street
Davis, California 95616 ●

CALL FOR PAPERS

The fall meeting of the Texas Herpetological Society is scheduled for November 2, 1983, at the University of Texas at Tyler, Tyler, Texas. Two paper sessions will be held:

I. Texas Herpetofauna, Now: Topics dealing with studies of the Texas herpetofauna, i.e. Ecology, systematics, natural history, etc.

II. Texas Herpetofauna, The Future: Topics dealing with endangered species, habitat destruction, protection laws, etc.

Talks will be limited to 20 minutes and can deal with any aspect of the Texas herpetofauna. Deadline for titles is September 1, 1983.

A tour of the new herpetarium at the Caldwell Zoo will be held at 6 PM on November 1 and a Texas style barbeque will be held after the meeting on November 2. Dr. Charles Carpenter, University of Oklahoma will be the speaker and will talk on "Ritualization in Reptiles."

Submit paper titles to: Dr. Neil Ford, Department of Biology, University of Texas at Tyler, Tyler, Texas 75701. ●

LEHIGH VALLEY HERPETOLOGICAL SOCIETY

In January of 1982, a small group of reptile and amphibian enthusiasts from the Allentown-Bethlehem-Easton (PA) area met and formed what at that time was called the Lehigh Valley Reptile and Amphibian Club. Several meetings were held at irregular intervals during 1982. In late 1982 a constitution and by-laws was adopted, and the group was reorganized as the LEHIGH VALLEY HERPETOLOGICAL SOCIETY. Since January 1983 regular monthly meetings have been held on the fourth Monday of each month at the Guthsville Rod and Gun Club in Guthsville, PA (near Allentown).

Current officers of the LEHIGH VALLEY HERPETOLOGICAL SOCIETY are:

President — Mike Jones
Vice-President — Cliff Swoyer
Secretary — Len Knapp
Treasurer — Dan Kohler

All persons living within the general Lehigh Valley Area, and who are interested in reptiles and amphibians, are invited to join our group. Dues rates are $5.00 per year for student members, $10.00 per year for adult members. For further information write to:

G. Leonard Knapp
215 Lawn Avenue
Sellersville, Pennsylvania 18960 ●

TEN-YEAR INDEX
JOURNAL OF HERPETOLOGY

A comprehensive index covering volumes 1-10 (1968–1976), compiled by J.P. Kennedy and June Moreland, recently has been published. The 75-page booklet, measuring 7 by 10 inches to match the *Journal* format, is **cross-indexed by author/title, by subject and by taxonomic name.** Prices: $7 postpaid in USA; overseas $8 postpaid (includes $1 to cover extra postage). Checks may be made payable to SSAR. Payment in USA funds; International Money Orders acceptable.

•

Send orders to Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA. A complete list of society publications and membership information can be obtained from Dr. Taylor. Currently, SSAR issues seven series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Herpetological Circulars, Contributions to Herpetology, Catalogue of American Amphibians and Reptiles* and *Recent Herpetological Literature.*

INSTITUTIONS

HERPETOLOGY AT THE SAN DIEGO NATURAL HISTORY MUSEUM

In 1960 Lawrence M. Klauber donated his herpetological collection of 35,000 specimens and his vast library of over 20,000 books and reprints to the San Diego Society of Natural History, whence they were housed in the Society's Natural History Museum in Balboa Park. At the time of Klauber's death in 1968, the number of specimens of amphibians and reptiles at the museum was over 50,000. The full history of the collection, though, predates the Klauber era to when the Society was founded in 1874. It is a history punctuated by colorful, sometimes scandalous, anecdotes about the collectors and curators of their time. A number of changes in staff and policy have occurred in recent years, however, especially since the late 1970s. There have been three curators since 1978, the most recent of these being Gregory Pregill, who arrived in September, 1981. Because this turnover has been somewhat confusing to the herpetological community, it seems appropriate to review the status of the collection, and the research developments underway by the current staff. In addition, a few propitious comments on certain historical events will reveal, in part, the strengths and taxonomic emphasis of the collection that affect its use.

For many years the collections of amphibians and reptiles at the San Diego Natural History Museum were synonymous with the life of Lawrence M. Klauber, yet he himself did not begin his herpetological studies until 1920 when he was 37 years old. Klauber was a herpetologist by avocation, his livelihood being derived from his training as an electrical engineer. He joined San Diego Gas and Electric as a salesman in 1911 and retired as Chairman of the Board in 1954. Klauber conducted most of his research and maintained his collections in the basement of his home. For its part, the San Diego Society of Natural History started amassing specimens of amphibians and reptiles in the early 1890s, largely through the encouragement of Frank Stephens and Charles R. Orcutt, both noted naturalists of the Southwest. Orcutt died in August, 1929, while on a field trip to Haiti, and a year later the museum obtained his scientific library and those of his collections of natural history specimens that were in San Diego at the time. Stephens was very active in the early years of the Society, was appointed as the first Director of the Museum in 1917 (then located downtown), and served the Society in one capacity or another until 1935 when he retired at the age of 86. He died two years later. From 1924 until his retirement Stephens held the title of Emeritus Curator of Vertebrates. Although his own principal inquiry was mammalogy, he still took an interest in building a herpetology collection. By 1930 the museum's collection of amphibians and reptiles numbered 2189 specimens. After that date the majority of specimens coming into San Diego from collectors and donors was given to Klauber, who by then held the title of Honorary Curator of Herpetology. As early as 1928 Klauber foresaw that someday his collection and that of the museum would merge, and he assigned specimen numbers accordingly so that they would not have to be recataloged at a future date. Consequently, all specimens originally in the LMK collection have the same numbers in the herpetological collections of the San Diego Natural History Museum.

Klauber's legendary interest in rattlesnakes resulted in an enormous series of *Crotalus*, and substantial numbers of most species of reptiles native to the Far West and northern Mexico. His collection had many contributors. Among the more significant ones were Cyrus Perkins and Charles Shaw, the successive curators of reptiles at the San Diego Zoo, a position now held by James Bacon. Perkins traveled widely during the 1930s in Mexico, South America and the Pacific. Shaw brought in many specimens from throughout the Southwest during the 1940s and 1950s. Shaw in fact curated the museum's herpetological collection for a time during WW II when the U.S. Navy temporarily annexed the museum for a hospital and the museum's collections were stored in various places around San Diego. The herpetology collection was displaced to the zoo, located adjacent to the museum in Balboa Park. The museum had moved to a new building there, its present quarters, in 1932.

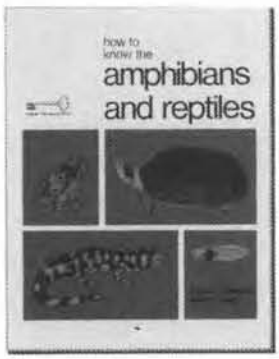
After 1960, following the merger of the two collections, the Department of Herpetology was overseen nominally by various people. Richard Etheridge, now Professor of Zoology at San Diego State University, had arrived there as an assistant professor in 1961 and supervised the collection for a time thereafter. Allan J. Sloan was the assistant curator. Sloan helped to move and integrate the Klauber collection into the museum, and responded to the day-to-day needs of the department for several years. In 1973 Thomas H. Fritts became the first full-time resident curator in the Department of Herpetology who had completed formal graduate training. Fritts and his assistants did much to modernize the collection by updating nomenclature, relabeling jars, and initiating a species index. They also began building the osteology collection and involved graduate students from San Diego State University in various tasks and field work. Fritts resigned in 1978 and was succeeded by Crawford Jackson, who served as curator for two years. When Jackson vacated the position in 1980 the collection was managed by curatorial assistants Mark Dodero and Ann Fetzer. They left the museum to resume their studies when the present curator arrived, although Mark still remains active in departmental field work.

Currently the staff includes Pregill and two curatorial assistants, James E. Berrian and Van Wallach. Jim is responsible for cataloging and overseeing the species index. Van Wallach's expertise in snake taxonomy has him maintaining that part of the collection although he mainly functions as a research assistant. The department benefits regularly from the steady contribution of several volunteers who assist in typing, cataloging, and organizing the departmental library and correspondence file.

The collection contains approximately 64,000 specimens, which may be broken down taxonomically as follows:

Amphibians (Apoda, Caudata, Anura) - 17 families, 55 genera, 150 species

Turtles - 9 families, 34 genera, 80 species



Lizards (includes amphisbaenians and *Sphenodon*) - 15 families, 110 genera, 320 species

Snakes - 9 families, 130 genera, 300 species

The Pictured Key Nature Series

how to know the amphibians and reptiles

by Royce E. Ballinger and John D. Lynch, University of Nebraska

Offers identification keys, descriptions, and distributional notes for amphibians and reptiles of the United States and Canada.

- Clear instructions for the use of each key
- Hundreds of accurate and clearly labeled line drawings
- Metric measurements
- Vital economic and biological information
- Collection techniques
- Preservation hints
- Thorough index-glossary

For more information write or call:

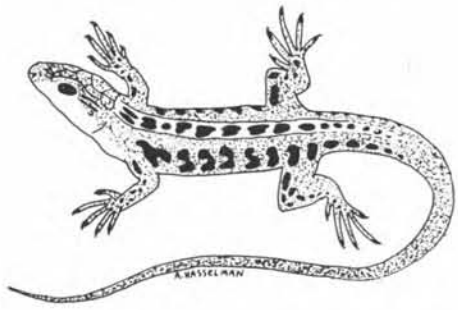
Dubuque, IA 52001
Telephone: (319) 588-1451 (ext. 883)

These taxa also encompass nearly 2000 skeletons in roughly the same diversity, and several hundred preserved hemipenes representing 70 species of snakes (mostly *Crotalus*) and lizards. A compilation of our 56 holotypes and several hundred paratypes has been completed and will soon be published in the Society's *Transactions*. Computer entry for at least some aspects of the collection is anticipated to begin early in 1983.



The collection emphasizes the regional fauna, reptiles in particular, yet it is flavored with series of taxa from various places of interest to former and recent curators and contributors. During WW II various military personnel contributed a nice series of Pacific skinks, for example, and Cyrus Perkins assembled a sizeable collection of reptiles from the Galápagos Islands. The osteology collection has become more cosmopolitan as a result of the exotic species available on occasion from the San Diego Zoo. Current research interests have also expanded our skeletal holdings through the accumulation of ontogenetic series of many species from the Southwest and the West Indies.

The present research programs are mainly in systematics and biogeography. Jim Berrian, however, is also conducting a demographic study of reptiles in the high desert near Anza Borrego, in addition to pursuing his interest in the relationships of the leaf-toed geckos, *Phyllodactylus*. We anticipate that the population study will continue to provide data indefinitely. Over 100 can traps have been placed in a one-hectare plot that transects microhabitats ranging from sandy washes to rocky hillsides. For several years now, Van Wallach has been studying in detail the soft anatomy of snakes, giving attention to the morphology of the trachea and lungs. He has examined representatives of 350 genera and about 835 species for a major treatise on the subject and its bearing on snake phylogeny. Pregill is continuing his work on the West Indian herpetofauna, its systematics, paleontology and zoogeography. This research has benefited from recent support by the National Science Foundation and National Geographic Society, primarily for research assistants, laboratory equipment and field work in the West Indies.

This department enjoys an adjunct relationship with the Department of Zoology at San Diego State University. Professors Richard Etheridge and Richard Estes and their graduate students routinely collaborate with us on the systematics and paleontology of squamates, and other areas of mutual interest.

We anticipate that within six months the alcohol collection will have been moved to a renovated facility on the museum grounds. The move is in compliance with the regulations of the San Diego Fire Department. Relocation of the alcohol collection will result in the disadvantages of a collection segregated from the departmental offices, but it may adumbrate the creation of space for the growing osteology collection and for visitor and student work areas. The department is equipped with a wet lab, microscopes, photographic equipment, some recording equipment, map and kodachrome-slide libraries, and field and collecting gear. The herpetological research library contains approximately 32,000 volumes. The department welcomes visiting researchers and inquiries about specimens. Loans are made to individuals with institutional affiliation.

Society for the Study of Amphibians and Reptiles

announcing a new book

TURTLES OF VENEZUELA

by Peter C. H. Pritchard and Pedro Trebbau

This new book will be the first in-depth treatment of a major South American turtle fauna. It covers all turtles known from Venezuela including the mata mata and other side-necks (11 species), tortoises, pond and land turtles (6 species) and the sea turtles (5 species), together comprising fully half of the turtle species described from the South American continent. There is an extensive discussion of zoogeography of South American turtles and an illustrated key to species (in both English and Spanish). Each species account consists of a synonymy followed by a diagnosis; a detailed description (including shell, soft parts, color and sexual dimorphism); and sections on size and growth, distribution and geographic variation, habitat, feeding, reproduction, economic importance, and vernacular names. There is also a comprehensive bibliography and list of locality records.

The book is beautifully illustrated. There are 48 full-page plates in color, 26 of which are original watercolors and the remainder a collection of 160 photographs of both turtles and their habitats. In addition, there are two distribution maps for each species: a spot map showing the detailed Venezuelan distribution and a map showing the continent-wide range.

The book is about 350 pages, 8½ x 11 inches (or 21.5 x 28 cm) bound in cloth, price US$45 postpaid. A special leatherbound patron's edition, in two volumes, is US$300 postpaid. **Publication date: November 1983.** A 4-page ad with sample color plates was published in the December 1982 issue of *Herpetological Review,* or may be obtained on request from Dr. Douglas Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA.

Orders may be placed with Dr. Taylor. Please make checks payable to "SSAR"; payments must be in USA funds or by International Money Order. A complete list of Society publications and membership information can be obtained from Dr. Taylor. The Society publishes *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Herpetological Circulars, Contributions to Herpetology, Catalogue of American Amphibians and Reptiles* and *Recent Herpetological Literature.*

Society for the Study of Amphibians and Reptiles
BALLOT

This is the official ballot of the SSAR to elect officers for 1984. All SSAR members are urged to vote. This ballot must be received no later than 15 December 1983. Please use the attached self-addressed envelope.

For President-elect (vote for one):

- ☐ Herbert Dessauer
- ☐ George Pisani

For Secretary (unopposed):

- ☐ James S. Jacob
- ☐ _____

For Treasurer (unopposed):

- ☐ Henri C. Seibert
- ☐ _____

For Board of Directors (Class of 1986 vote for one from each category):

REGULAR

- ☐ Alan Savitzky
- ☐ Samuel Sweet

OVERSEAS

- ☐ Timothy Halliday
- ☐ Ricardo Martori

PROPOSED AMENDMENTS TO SSAR BYLAWS

The proposed amendments appeared on pp. 4 & 5 of *HR*, 14(1), 1983. Please refer to that issue for a complete description of the three amendments.

1. ☐ **for** ☐ **against** the proposed amendment to Article II, Section 3, which would specify a term of office of one year for the Publications Secretary; the term of office was not previously stated.

2. ☐ **for** ☐ **against** the proposed amendment to Article II, Section 6d, which adds membership on the SSAR Board of Directors as being one of the duties of the Publications Secretary.

3. ☐ **for** ☐ **against** the proposed amendment to Article III, Section 1, which adds the Publications Secretary to the SSAR Board of Directors.

REMOVE THIS PAGE FROM *HR* TO VOTE

The Candidates

HERBERT DESSAUER, Professor of Biochemistry, Department of Biochemistry, Louis iana State University School of Medicine, New Orleans, Louisiana; Ph.D., Louisiana State University (1951). Research interests: (a) influence of photoperiod on seasonal cycles of lizards and snakes, (b) evolution of *Anolis,* New Guinea *Litoria* and snakes, especially the natricines, and (c) population genetics of closely related species in zones of contact. He is a Reasearch Associate of the American Museum of Natural History and of the L.S.U. Museum of Zoology. He was a member of the 1969 ALPHA HELIX Expedition to New Guinea, panels of the National Science Foundation in Systematic Biology and Advanced Science Education, and the National Committee for Resources in Herpetology. SSAR activities: Board Member (1981). Publications: 110.

TIMOTHY HALLIDAY, Senior Lecturer in Biology, the Open University, Milton Keynes, England. Research interests: Studies of the sexual behaviour and evolutionary biology of European newts (*Triturus*) since 1968, and of the breeding dynamics of toads (*Bufo bufo*) and frogs (*Rana temporaria*) since 1977. Member of the British Herpetological Society, Societas Europea Herpetologica, Herpetologists' League, and European editor of the journal *Animal Behaviour.* SSAR activities: Member of the Editorial Board of the *Journal of Herpetology* (1975).

JAMES S. JACOB, Associate Professor of Biology, Memphis State University, Memphis, Tennessee; Ph.D., University of New mexico (1977). Research interests: Comparative morphology and physiology of reptiles and amphibians. SSAR activities: Chairman of Memphis Local Committee (1981), Secretary (1982-present), Chairman of Longrange Planning Committee (1983), Meetings Committee member (1983). Publications: 15.

RICARDO A. MARTORI, Instructor (Prof. Asst.), Departmento de Ciencias Naturales, Facultad de Ciencias Exactas, Fisicoquimicos y Naturales, Universidad Nacional de Rio Cuarto, Rio Cuarto, Cordoba, Argentina; Born: 1 Jan. 1944 in Cordoba, Argentina; B.S. University of Texas, Austin with additional study and research at the Universidad Nacional de Cordoba; Research interests: Distribution and Ecology of the Reptiles and Amphibians of Argentina, especially aspects of feeding biology; SSAR activities; Member in good standing for three years; Publications: 5, all on the ecology and distribution of Argentine amphibians and reptiles.

GEORGE PISANI, Director of Laboratories and Instructor, University of Kansas Division of Biological Sciences. Research interests: Natural history of North American snakes; reproductive biology of snakes. Member of Herpetologists' League since 1964. Charter member of Kansas Herpetological Society. Member of Associaton of Systematics Collections and Sigma Xi. Editor of *ASC Newsletter.* SSAR activities: Member of OHS/SSAR since 1962; editor of *Herpetological Review* for 6 years and *Herpetological Circulars* for 7 years; editor and originator of SSAR's latest venture into a literature referencing service. Publications: 25 (13 refereed), and has edited about 10 books for ASC.

ALAN H. SAVITZKY, Assistant Professor, Department of Biological Sciences, Old Dominion University, Norfolk, Virginia; Ph.D., University of Kansas (1979). Research interests: Systematics and evolutionary morphology of snakes, especially the parallel evolution of specialized feeding and defensive structures; venom delivery systems, hinged dentitions, crushing dentitions, and morphological correlates of aquatic foraging. Member of American Society of Ichthyologists and Herpetologists, American Society of Zoologists, Herpetologists' League, Society of Systematic Zoology. Board of Governors, ASIH (1982-1986). Associate editor, *Contributions to Herpetology* (1982-present). Research Associate, National Museum of Natural History (1983-1986). Publications: 17

HENRI C. SEIBERT, Professor of Zoology, Ohio University, Athens; Ph.D., University of Illinois, Urbana (1937). SSAR activities: Board of Directors (1962 to date); Publications Secretary (1966-1976); Treasurer (1970 to date). Publications: dozens.

SAMUEL S. SWEET, Assistant Professor of Biological Sciences and Curator in Herpetology, University of California, Santa Barbara; Ph.D., University of California, Berkeley (1978). Research interests: Systematics and evolutionary morphology in hemidactyliine plethodontid salamanders (Texas and Appalachians) and analysis of clinal and geographic variation in southwestern snakes; variation and selection in intergrade zones in *Pituophis* and the quantification of cryptic and mimetic color patterns in reptiles; currently compiling a detailed regional book on the herpetofauna of southwestern California. Publications: about 20, including abstracts.

NEWSNOTES

JOSEPH GRINNELL MEDAL

George A. Bartholomew, Professor of Biology at the University of California at Los Angeles, has been selected to receive the **JOSEPH GRINNELL MEDAL IN VERTEBRATE ZOOLOGY** in honor of his distinguished research achievements in scientific natural history. The Grinnell Award commemorates the 75th anniversary of the founding of the Museum of Vertebrate Zoology, University of California, Berkeley, where Grinnell served as its first director and pioneered the development of natural history as a scientific discipline. The award will be presented at a formal ceremony on Friday, 11 November 1983 in Berkeley. ●

HABITAT SYMPOSIUM

A symposium, WILDLIFE 2000: MODELING HABITAT RELATIONSHIPS OF TERRESTRIAL VERTEBRATES, will be held 7-11 October 1984 at Fallen Leaf Lodge (Stanford University's Sierra Camp near Lake Tahoe). It will provide for scientists and managers an up-to-date synthesis of issues in the development, testing, and application of models that predict responses of wildlife to habitat changes. Technical presentations will be given in six non-overlapping sessions. Posters will also be presented; some will be included in the symposium proceedings to be published promptly in journal format. Abstracts of papers are due 15 December 1983; those for posters are due 31 January 1984. *Registration will be limited* and applications filled in order of receipt. Interested persons may obtain registration materials and instructions for submitting abstracts from Dr. Jared Verner, Program Chair, Forestry Sciences Laboratory, 2081 East Sierra Ave., Fresno, California 93710, USA. ●

NATIONAL SYMPOSIUM ON *CALOTES VERSICOLOR*

A Symposium is to be organized on *Calotes versicolor* during late 1984 / early 1985 at Poona/Mysore. It will cover all aspects of this lizard: systematics, ecology, behaviour, anatomy, biology, reproduction, development, endocrinology, immunology, pathology, parasites, etc. It is proposed to publish the proceedings of the Symposium as a monograph containing all available information on *Calotes versicolor*. All scientists working or having worked on *Calotes versicolor* are, therefore, requested to participate in the Symposium. For achieving harmony and coordination a network is being formed of all persons willing to participate in the Symposium. All interested scientists are requested to communicate their participation content to any one of the following.

Professor H. B. Devaraj Sarkar
Department of Zoology
University of Mysore
Manasagangotri, Mysore 570 007 India

Dr. Suresh C. Goel
Department of Zoology
University of Poona
Poona 411 007 India ●

NEW FEDERAL LISTINGS PROPOSED FOR REPTILES AND AMPHIBIANS

On 30 December 1982 the U.S. Fish and Wildlife Service of the Department of the Interior published a review of vertebrate wildlife being considered for listing as endangered or threatened species under the Endangered Species Act (Federal Register, Vol. 47, No. 251). Fifty-two amphibians and 58 reptiles are listed in the proposed rules. Five taxa are listed as extinct, 6 taxa are being considered for listing, and 9 taxa are listed as being more abundant than previously believed and/or not subject to any identifiable threat. Persons working with the proposed taxa should be aware that listing often hampers captive propagation (or other research) programs; they are encouraged to write to the Service and emphasize this aspect of the listing, as well as the importance of habitat protection.

The Fish and Wildlife Service is soliciting comments on the proposed listings from the public. All interested persons in the herpetological community are encouraged to contribute comments and information on the status of the proposed taxa. Comments should be submitted to: Director (OES), U.S. Fish and Wildlife Service, Department of the Interior, Washington, D.C. 20240.

Submitted by **GARY CASPER,** 1857 Third Street, White Bear Lake, Minnesota 55110 U.S.A. ●

OHIO REPTILE SURVEY

An exhaustive survey of reptilian distribution in Ohio has been initiated. I am specifically interested in the following:

A. Distribution data since 1951 of reptiles in Ohio which have not appeared in the literature. Ideally the data should be documented by specimens or clear identifiable photographs, though any information would be valuable.

B. The existence of little-known collections which contain Ohio specimens.

C. Individuals who have collected in Ohio.

If you can be of any assistance please contact:

Douglas Wynn

ECTOPARASITES WANTED

Mites and ticks from reptiles wanted! Preserve in isopropyl alcohol if 70% ethyl alcohol is not available. Assistance also provided to institutions and private collectors wanting assistance with identification of reptilian intestinal parasites; there is no charge for this service.

Send ectoparasites to, or request assistance from:

Sue Barnard
Senior Reptile Keeper
Atlanta Zoological Park
800 Cherokee Avenue, SE
Atlanta, Georgia 30315, USA ●

REPTILE PARASITE SYMPOSIUM

There will be a Symposium on Parasites of Reptiles held during the first week of December, 1983, in conjunction with the annual meeting of the American Society of Parasitologists and the American Society of Tropical Medicine and Hygiene. Titles and speakers are:

Intestinal Protozoa of Reptiles *by* Dr. R. S. Wacha (Drake University)
Hemoprotozoans of Reptiles *by* Dr. S. S. Desser (University of Toronto)
Helminth Parasites of Reptiles *by* Dr. D. R. Brooks (University of British Columbia)
Arachnid Parasites of Reptiles *by* Dr. Harry Hoogstraal (Cairo, Egypt)
Pentastomids of Reptiles *by* Dr. J. T. Self (University of Oklahoma)
Veterinary Aspects of Reptile Parasitism *by* Dr. B. Raphael (Dallas Zoo)

All herpetologists are invited to attend this symposium being held at the Convention Center in San Antonio, Texas. Further information may be obtained from:

Dr. Robert E. Kuntz
14794 Cadillac
San Antonio, Texas 78248, U.S.A.

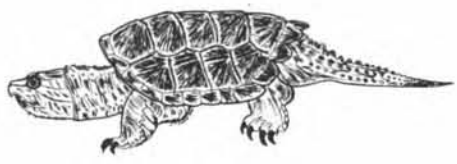
B.H.S. PUBLISHES SEA TURTLE CONSERVATION BOOK



The British Herpetological Society has recently published a critical review of the current problems and controversies of sea turtle conservation. *Conserving Sea Turtles,* by Nicholas Mrosovsky, is of interest to general readers as well as the specialist biologist. The book is concerned with the methods being used to achieve that end; it argues that much is wrong.

The price of this book is:

U.K. £5.00 + 75p postage (surface)
or £2.80 (airmail)
U.S.A. $10.00 + $1.00 postage (surface)
or $5.00 (airmail)

International money orders and checks should be made payable to the British Herpetological Society and sent to:

Dr. S. Townson
British Herpetological Society
c/o Zoological Society of London
Regent's Park, London, NW1 4RY
ENGLAND ●

FACSIMILE OF *BRITISH JOURNAL OF HERPETOLOGY* VOLUME ONE 1948-55

The *British Journal of Herpetology* is published by the British Herpetological Society. The first eight numbers of Volume One, 1948-53, were edited by Prof. Angus Bellairs. Just thirty years since being the editor and on the occasion of his retirement, the Society wishes to honour Prof. Bellairs's contribution to herpetology and announces that *hard-bound* facsimile copies of Volume One of the *British Journal of Herpetology* will be made available at the end of 1983. At twelve numbers per volume (two yearly), Volume One consists of 228 pages. The facsimile will be approximately A5 in size. (Back numbers of the journal are at present sold at £3.00 ($5.50) each).

Copies will be available at a special pre-publication price of £7.50 ($11.50) to non-members of the British Herpetological Society and £5.00 ($8.00) to members. After publication by 31st December 1983, the price will be £12.50 ($19.00) to non-members and £10.00 ($15.50) to members. Prices do not include £0.50 ($1.00) surface postage and packing. Should pre-publication requests be insufficient to cover production costs and the project fails, subscribers will be returned their contributions. But every effort will be made to avoid this.

The British Herpetological Society (founded 1947) is probably the first nationally formed society for the study of amphibians and reptiles in Europe, as well as in the Commonwealth. The *British Journal of Herpetology*, presently edited by Dr. R.A. Avery, is now in its sixth volume. The first volume, besides recording aspects of the early development of the society and herpetology in Britain, includes some classical papers and others of historical interest. The first distribution maps of the herpetofauna of Britain and Ireland compiled by vice-counties by Col. R.H.R. Taylor (1948) make up the first number. Subsequent numbers include a paper on hybridization between the 'green frogs' *Rana esculenta* and *R. ridibunda* by L.C. Mandeville and Helen Spurway, phenological reports on frog *(Rana temporaria)* and toad *(Bufo bufo)* breeding in Britain and a note on the distribution of herpetofauna in the Channel Islands by Dr. J.F.D. Frazer (BHS President 1955-81), a review of snake limbs by Prof. A. d'A. Bellairs, a paper on the influence of the climate of Britain and Ireland on the habits and distribution of the herpetofauna and various notes by the Society's founding President, Dr. Malcolm Smith, and a pioneer paper on toad *(Bufo bufo)* migration by H.J. Moore at Clayesmore School, Dorset.
The last four numbers were edited by Dr R. Maxwell Savage.

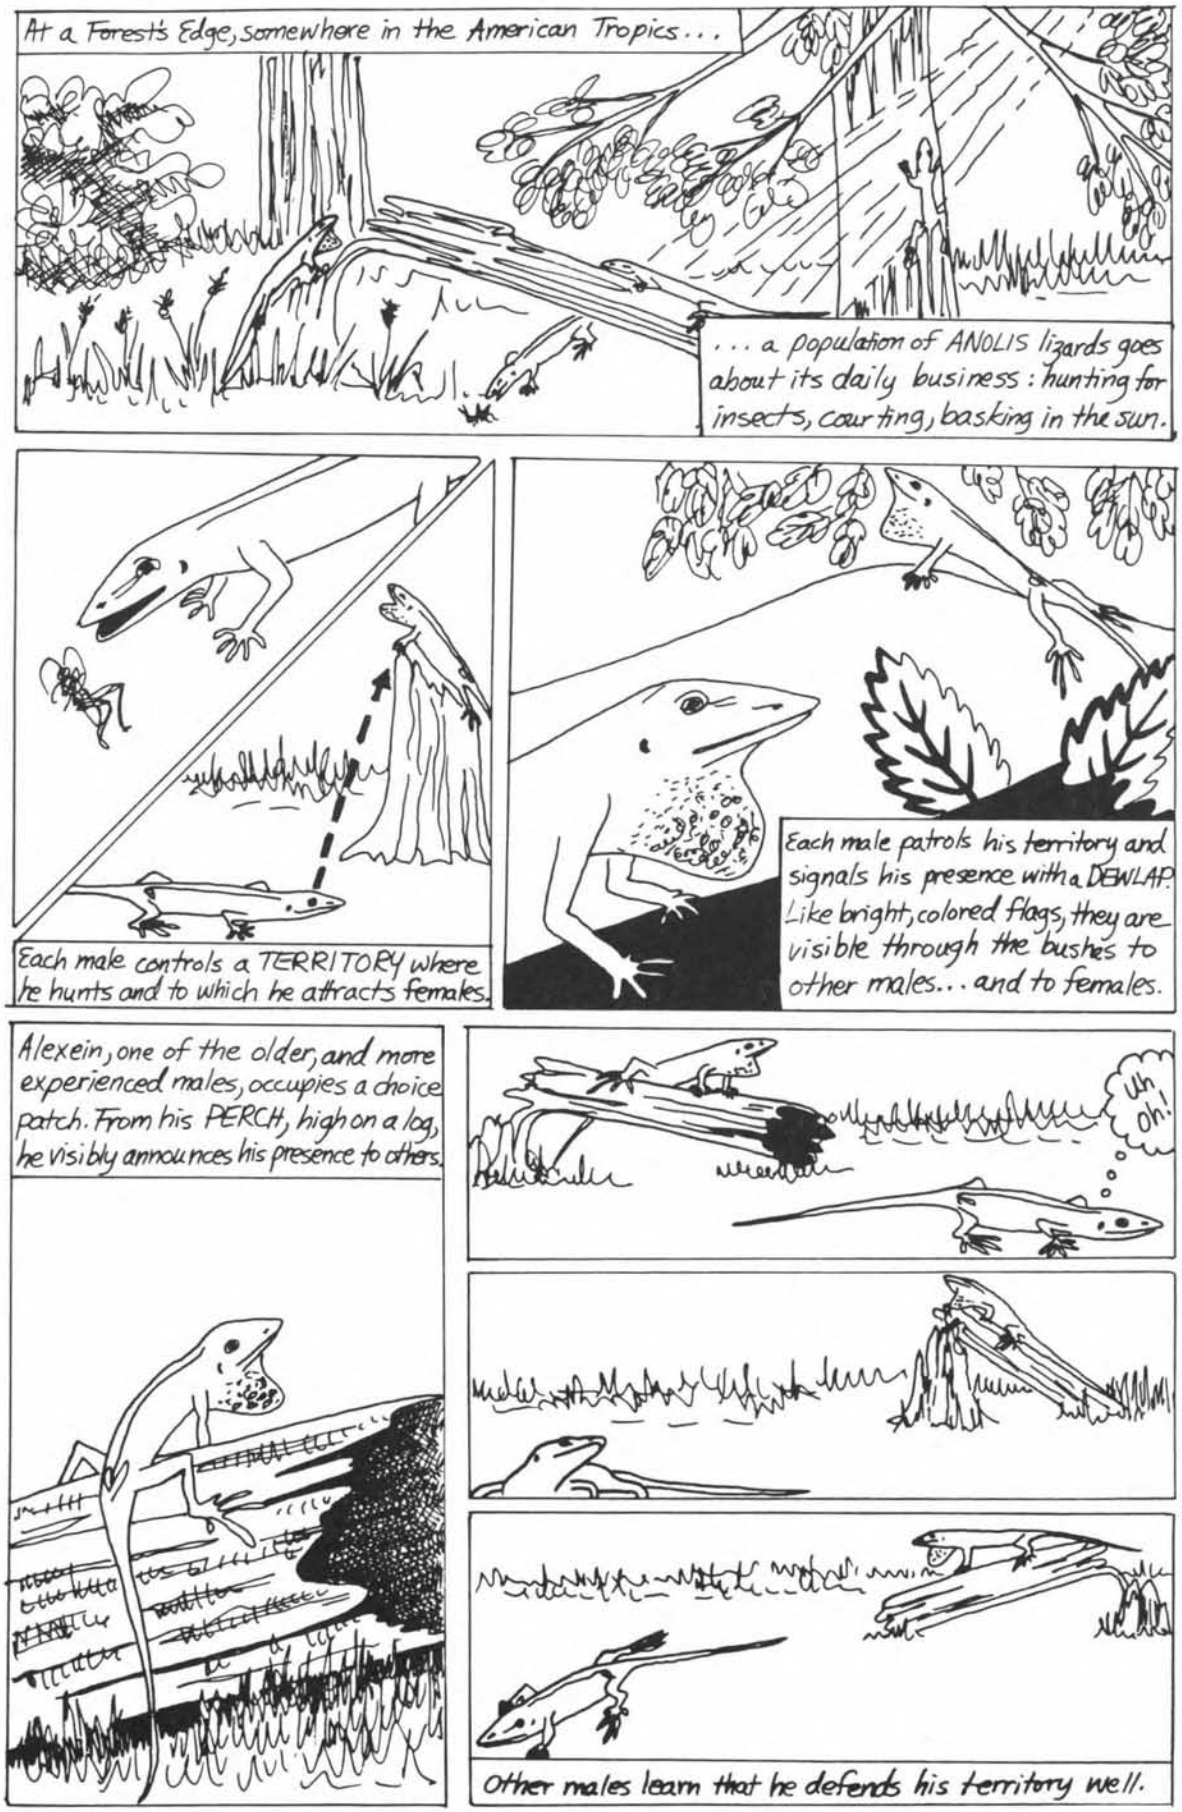
HERPlab: A HERPETOLOGY LEARNING CENTER



In the center of the newly renovated Reptile House at the National Zoological Park is a new family classroom where zoogoers can learn about herpetology. This classroom, called HERPlab, was developed by the Zoo's Office of Education and Department of Herpetology through a grant from the National Science Foundation. The purpose of the HERPlab project was to develop a core of interactive educational materials that would enable families to learn more about zoology when they visit a zoo. Although the materials focus on herps, the concepts around which they are designed are general ones—e.g. anatomy, behavior, communication, feeding—and apply to other taxons as well.

To help ensure that the materials had general applicability and might be of use to places besides the National Zoo, two other zoos joined the project as field test sites: the John Ball Zoo in Grand Rapids, Michigan, and the Philadelphia (PA) Zoo. Both received copies of the HERPlab educational materials and set up areas to try them out with their zoogoers.

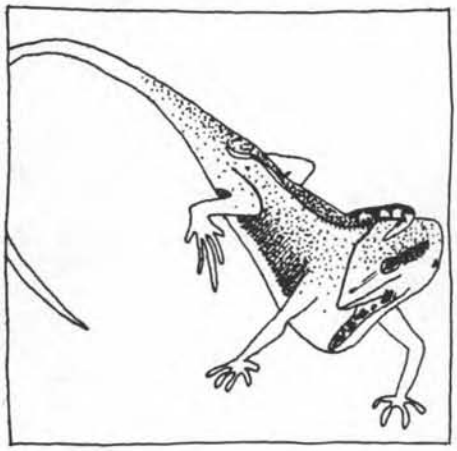
The HERPlab materials are aimed at the variety of ages you might expect in a family group. Thus zoogoers of various learning levels will find something of interest. Activities range from simple sorting games and puzzles to more complicated conceptual activities dealing with topics such as anatomy and social behavior. A small library with children's books as well as advanced reference texts supplements the HERPlab materials.

The lab is about the size of a small classroom and holds 20 to 25 people comfortably. To avoid crowding, a free ticket system regulates visitors on busy days. The lab is a pleasant environment, furnished with tables and chairs. Along the walls are a few exhibits, but the majority of the materials are contained in activity boxes located behind a check-out counter—as in a library. When visitors enter the lab, they receive a list of these activities and may select what interests them to use during their visits. They can take an activity box to a table and are free to explore its contents. The lab is staffed by one or two volunteers from the Friends of the National Zoo (FONZ). They work as facilitators to help visitors use the materials and find answers to their questions.

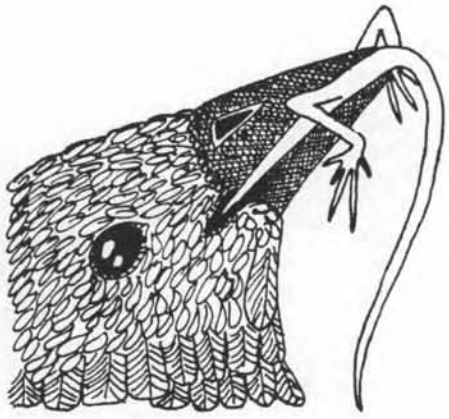
There are currently 14 activity boxes, with a few additional ones being developed. Most are based around objects like bones or eggs, or are games. Four, however, focus on a live animal: SNAKE, FROG, LIZARD, TURTLE. SNAKE, for example, lets visitors look closely at and learn about a live corn snake. The animal is housed in a clear plastic box which is secured on a special plastic stand with a mirror on the bottom. This arrangement allows viewing from all sides without moving the box and possibly stressing the animal. The corn snake *(Elaphe guttata)* is a tractable species as are all those used for the live animal activity boxes. Individuals are rotated so that no one animal is used consecutively.

At a Forest's Edge, somewhere in the American Tropics...
... a population of ANOLIS lizards goes about its daily business: hunting for insects, courting, basking in the sun.
Each male controls a TERRITORY where he hunts and to which he attracts females.
Each male patrols his territory and signals his presence with a DEWLAP. Like bright, colored flags, they are visible through the bushes to other males... and to females.
Alexein, one of the older, and more experienced males, occupies a choice patch. From his PERCH, high on a log, he visibly announces his presence to others.
Uh oh!
Other males learn that he defends his territory well.

Reptile Keepers



Time out. Stop and size up the situation.



Stand Still

Put your best side forward. Flatten yourself sideways and appear taller.

Gain 1

A big bird picks you off.

Game over. You lose.

Play the game again. If you draw this card again, ignore it and keep playing.

Accompanying the boxed animal is a packet of observation cards that encourage visitors to look closely at and think about the animal. Questions like "Why do you think the snake keeps sticking out its tongue?" focus attention on the sensory capabilities of the animal and lead to further questions and answers. Short answers in fairly simple language are provided for parents to read to children. Information in smaller print provides more details for those with more interest.

There are similar activity boxes for three additional species: African bullfrog *(Pyxicephalus adspersa)*, Eastern box turtle *(Terrapene carolina)*, and leopard gecko *(Eublepharis macularis)*. All species are rotated on a daily basis, similar to the method used with the corn snake.

The activity box TERRITORY is a board game with the board painted to resemble the woodland home of an anolis lizard. Each player takes the role of a lizard: one is the resident defending his territory, the other is the intruder. The game is constructed to teach certain things about territoriality and behavior. Displays are described clearly with drawings and in functional contexts. Players take turns drawing cards that describe these behaviors and determine their moves on the board. For example, "You flag your dewlap, but the resident ignores it. Better luck next time. LOSE 2." "Give it your all. Do a full display—head bobs, flags, and push-ups, all at once! GAIN 4." By the end of a game, both players have sampled the repertoire of *Anolis* aggressive behavior. Included in the game is a comic book called "Leaping Lizards" that describes a typical aggressive encounter.

Activity boxes include a range of materials and topics. TURTLE BONES is an anatomy puzzle built around a skeleton. COMMUNICATIONS includes the sounds of frogs and lizards. EGGS offers shells, larvae, and a guided quiz to explore the topic of reproduction. Additional boxes include VENOMOUS SNAKES, REPTILE OR AMPHIBIAN?, ENDANGERED HERPS, REPTILE KEEPERS (husbandry), SKULLDUGGERY (teeth and eating), and HERP SORTING CARDS.

In addition to the activity boxes, there are some interactive exhibits and film loops. The purpose of these 8 mm films is to show some common behaviors which a visitor frequently misses in the Reptile House. Four loops were produced for this project: Eating, Snake Feeding, Locomotion, and Lizard Aggressive Behavior. A written guide accompanying each loop discusses important points to observe.

One of the interactive exhibits is called LIZARD WORLD. It is a display which includes three tanks of pairs of *Anolis carolinensis*. Visitors can participate in an on-going experiment about *Anolis* color change. Equipped with an observation sheet, they are encouraged to try out the scientific method, observe, and record carefully. The data collected by the visitors are recorded, tallied, and graphically represented next to the tanks.

Another display, REPTILE KEEPERS, contains information on husbandry and keepers' tools such as snake hooks, triple beam balance, and boots. Visitors can try on the boots and use or examine the other objects. Nearby, two glass doors permit viewing behind the scenes so visitors can actually watch keepers at work.

HERPlab has been open since October 1, 1982. Formal evaluations were conducted there and at the field sites for the first two months. As a result a few changes are being made in the materials. In general, however, the overall response of the visitors at all three sites was overwhelmingly positive, and our concern at the present time is finding ways of sharing the results of this project with other interested zoos and nature centers. We encourage any of you who are interested in finding out more about this project to visit the lab or contact us at the National Zoo.

Natural Nest Sites and Brooding Behavior of *Eumeces fasciatus*

Nesting sites of *Eumeces fasciatus* have been frequently observed (e.g., Cagle, 1940; Fitch, 1954; McCauley, 1939). We report further observations stressing arboreal nesting, the distribution of nest sites, and brooding behavior in natural and artificial sites.

On 22 June 1982, a decaying stump of a hardwood tree and a log leaning on the stump were examined on a small island (ca. 500 x 50 m) in a cypress swamp at the mouth of Steel Creek on the Savannah River Plant, Barnwell Co., South Carolina. Respective diameters of stump and log were approximately 1 m and 0.8 m. Some of the woody surfaces were bare, and most of the remaining bark was loose and easily removed. Sections of the wood had been reduced to sawdust by beetle larvae. Removal of bark and outer layers of loose wood exposed five adult female *E. fasciatus* and four clutches of eggs. The clutches contained 5, 6, 8 and 10 eggs. One of the clutches

was found on the elevated log about 1.5 m above the ground. The remaining clutches were found in distinctly separated locations on the stump, but all were approximately 1 m above ground. All four clutches were deposited on sawdust.

A more thorough search of the rotting logs and stumps on the entire island was conducted on 2 July 1982. Two isolated clutches were discovered. A female was brooding one clutch of nine eggs on sawdust in a rotting log approximately 2.3 m long and 15 cm in diameter. This log lacked bark and was hard on the outside, but soft on the inside. The other clutch was located approximately 10 m above ground in the decaying stump of a hardwood tree, which had a diameter of 0.6 m at the base. Four eggs, one hatchling, and a female were located in soft wood.

Although *Eumeces fasciatus* is often considered less arboreal than the larger *E. laticeps* (e.g., Smith, 1946; Mount, 1975), it readily climbs trees while foraging and avoiding predators (Fitch, 1954; Fitch and von Achen, 1977). In Swamps in central Alabama, Georgia and on the Savannah River Plant, we have frequently observed *E. fasciatus* on living and dead trees at heights greater than three meters. However, nest sites have not been previously reported at this height. We suggest that a quantitative assessment of perch heights and nest heights in woodland habitats is necessary to evaluate the vertical niche characteristics of *E. fasciatus* and the other southeastern members of the *fasciatus* group.

The occurrence of four clutches in close proximity combined with our inability to locate more than two isolated clutches in the surrounding area strongly suggests a clumped distribution of clutches. Since there was a notable lack of other large stumps at a suitable stage of decomposition in the area searched, the observed grouping of clutches presumably represents a response to scarcity of nesting resources, an explanation suggested by Fitch (1954). Fitch also suggested that gregarious and communal nesting might provide increased protection of each clutch from small predators while the female leaves the nest to forage. If gregarious nesting occurs primarily because it is selectively advantageous due to reduction of egg predation, it should be the norm even when nesting sites are abundant. However, no data are available to indicate the relative importance of resource limitation and protection of eggs to the establishment of nests in close proximity or to reveal possible density-dependent effects on nest predation.

Peeling bark and wood by hand and potato rake obscured the three-dimensional relationships between females and eggs in all but one of the elevated nests, but it was apparent in that instance that spatial relationships between female and eggs are more complex in natural nesting sites than descriptions in the literature indicate. The relatively undisturbed brooding site consisted of a small open cavity with a wide mouth and front chamber behind which the opening became shallower, narrowing into shallow passages, one running to the right and slightly up for several cm, and another running several cm above and behind the main chamber. When the cavity was exposed, the female was coiled in the front chamber, which had a shallow sawdust substratum and contained no eggs. Six eggs were found on or in nearly dry sawdust in deeper portions of the brooding chamber. In the recess extending to the right, four eggs, including one which had shriveled, were located at the level of the female and slightly above her. Two eggs were found in the other recess, approximately 8 cm above the female and slightly behind the main cavity. The closest members of the two groups of eggs were separated by a distance approximately equal to the female's snout-vent length (66 mm).

Skinks brooding eggs on two-dimensional cage bottoms usually gather the entire clutch into one or two tightly clumped groups about which or between which the female lies in one of three characteristic postures. Noble and Mason (1933) reported that although no fixed position is assumed, the most frequent arrangements of the female's body are a semicircle surrounding the eggs, an s-curve in which eggs are located in both concave portions, and a straight line among or over the eggs. However, these arrangements may be impossible in the confined three-dimensional chambers of some natural brooding sites. Spatial constraints may prevent females from gathering all the eggs into closely juxtaposed groups. Because pockets of sawdust are found in channels between relatively solid wood, single eggs or small groups may be placed in separated locations. Furthermore, brooding sites in vertical structures such as tree stumps usually have irregular, sloping surfaces on which the eggs are deposited. As a result of these spatial features of brooding sites in logs and stumps, eggs may be simultaneously above and below the female and separated from the female and other eggs.

Our observations suggest further studies of three natural historical aspects of *E. fasciatus*. First, regular use of trees for foraging and escape in at least three southeastern states and arboreal nesting suggest that more of the woodland habitat is available to *E. fasciatus* than has been suspected, especially in swamps. Second, in natural nest cavities spatial constraints may necessitate more complex brooding behavior than has been observed in laboratory settings. For example, it may be impossible for some females to gather their clutches into one or two compact clusters and maintain nearly continuous contact with them. Egg rolling, egg movement, and brooding postures in three-dimensional simulated natural nest cavities may all differ from the published accounts based on observations on flat cage bottoms (Nobel and Mason, 1933; Evans, 1959). Since *E. fasciatus* nests frequently in spaces containing large amounts of sawdust, females presumably must modify natural nest sites to a greater extent than revealed by the formation of small clearings in sphagnum moss or wood debris (Evans, 1959; Noble and Mason, 1933). *Eumeces fasciatus, E. laticeps,* and *E. inexpectatus* in our laboratory (Cooper and Vitt, unpublished observations) burrow in sand readily by using the snout as a wedge and dig holes with the forelegs in a manner similar to that described for *Anolis carolinensis* (Tokarz and Jones, 1979). Such behaviors are probably employed in nest construction.

Finally, the aggregated distribution of detected nest sites suggests that optimal nest sites may be scarce. Future studies should compare the distribution of suitable nest sites to that actually observed to determine the degree of aggregation. Comparison of nest predation rates on isolated and aggregated nests would reveal whether there is a selective advantage of communal nesting due to more effective guarding of the nests by several females, as suggested by Fitch (1954).

ACKNOWLEDGMENTS

This work was conducted under contract EY-76-C-09-0819 between the U. S. Department of Energy and the University of Georgia while the first author was a faculty research participant at the Savannah River Ecology Laboratory. Clerical support was provided by Auburn University at Montgomery.

*"Absolutely delightful"**

Their Blood Runs Cold

Adventures with Reptiles and Amphibians

WHIT GIBBONS

"Dr. Gibbons' book is a pleasant and instructive mixture of herpetologic lore, lively anecdote, humor, and conservation ethics. He writes with clarity and verve, and the book will give the general reader a more intelligent and sympathetic understanding of reptiles and amphibians, and of the scientists who study them."—**Archie Carr**

*"This book is absolutely delightful—a rare mix of fun and frolic and sound zoology. I wish there were more authors capable of such writing."—**Roger W. Barbour**

Whit Gibbons possesses the rare talent of conveying the challenge and excitement of scientific inquiry. A research ecologist who specializes in the study of reptiles and amphibians, he gives accounts of work in the field that are as readable as good short stories. *Their Blood Runs Cold* is entertaining, informative reading that not only enhances our understanding of a unique group of animals but also provides excellent insight into the mind and character of a research scientist. Thirty illustrations complement the text.

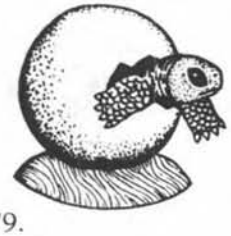
NATURAL HISTORY NOTES ON THE FIJIAN GROUND FROG (RANIDAE: *PLATYMANTIS VITIANUS*)

Fig. 1. Adult female *Platymantis vitianus* (USNM/FS 30762). Dorsolateral aspect.



Fiji has two endemic species of frogs: *Platymantis vitianus*, the ground frog, and *P. vitiensis*, the tree frog. The tree frog is relatively common on the islands of Ovalau, Taveuni, Vanua Levu, and Viti Levu (Pernetta and Watling, 1979) and is an inhabitant of leaf axils of pandanus in low-lying marshy areas or along mountain streams (Gorham, 1968; Pernetta and Goldman, 1976). In contrast, the ground frog is rarer on these same islands and usually stated to be an inhabitant of rocky forest streams and rivulets (Gorham, 1968; Pernetta and Goldman, 1976). During a brief stay on Ovalau in May 1982, I had the opportunity to observe and capture several *P. vitianus* in circumstances "unusual" for this species and, herein, summarize my observations.

Of the five ground frogs seen, none were in close proximity to a stream with running or standing water. All were on hill sides or ridge tops, at approximately 200 m or more above sea level, and 100 m or more from the nearest permanent stream. An adult female and juvenile male (USNM/FS 30762-63, respectively) were captured on the northeast facing ridge (*ca.* 200 m elevation) immediately behind Levuka in the remnant of a rainforest with a thinly closed canopy and heavy ground litter (4-5 cm deep). The frogs were captured within 4 m of one another in the litter associated with a giant Fijian heliconia. The female was discovered beneath a fallen and rotten heliconia stalk and dead fern root mass in the midst of a low terrestrial fern clump; the male was in basal litter of a heliconia clump. Although it was not evident at first, both sites lay in a temporary stream channel — slope 45-60° — which probably bore water only briefly during the heaviest rains; the nearest permanent stream was downslope at least 300 m away. The frogs when first observed were beneath the litter near the soil (soil temperature 24.5° C; moist but not wet, *i.e.*, could not be rolled into a ball; air temperature 27° C). The female's escape behavior was to move forward and bury deeper in the litter, a scurrying movement with no attempt to jump. The juvenile male made short jumps/dives into the litter, although there was no attempt to move from the base of the heliconia clump. Two immature females (USNM/FS 30778-79) and an escapee were discovered in litter associated with yaqona (Piper methystictum) plantations (*ca.* 250-300 m elevation) along the Draiba-Lovoni trail on the southeastern slope of a mountain. One female was hidden beneath a small log in the middle of a yaqona patch, lightly shaded by widely spaced legume trees with a thin ground cover of fallen legume leaves; she was partially buried in rotten wood and soil (soil and air temperature of 25° C; soil moist but not wet). The other female and an escapee were beneath a heap of cut cassava branches lying in thick (10-20 cm high) grass at the edge of a yaqona patch. This was a damper site with more vegetative litter and both frogs made quick short jumps moving downward and forward through the litter. The quick movements and depth of the litter in the brush heap made capture difficult. A *Bufo marinus* shared this hiding place and showed a similar escape behavior. The nearest permanent stream was 100-150 m downslope from both sites, and only the second site may have lain in a runoff channel, although a strong erosion pathway was not evident. The second site was likely shaded for at least part of the day by a small tree.

Upon capture, all four frogs were dark shades of brown. The two Levuka specimens lightened somewhat to a olive brown dorsal ground color with dark brown spots and

BEN GREISHAW • 7622 HOLLINS RD. • RICHMOND, VA. • 23229 (804) 282-8892

Fig. 2. Closeup of head of an adult female *Platymantis vitianus* (USNM/FS 30762). Anterolateral aspect.

beige axillary spots (Figs. 1 & 2). One of the Draiba females shared this coloration, the other lightened to a golden beige ground color. All possessed light axillary spots. The physical dimensions are summarized in Table 1. Only the Levuka female is sexually mature, but not gravid. Her ovaries contain at least two sizes of follicles (vitellogenic ones *ca.* 0.9-1.2 mm in diameter and previtellogenic ones 0.2-0.4 mm). The Draiba females are immature with numerous small (0.1 mm) previtellogenic follicles giving the ovary a granular appearance. The male is likely immature; its testes are ellipsoidal, 6.5 mm in length, apparently lobulated with each lobe externally outlined by melanocytes. Both Fijian *Platymantis* are believed to be voiceless (P. Ryan, *pers. comm.*), and this male lacks vocal sac openings, although absence in this case can also be attributed to immaturity.

The Fijian ground frogs appear to be opportunistic carnivores. All four frogs had stomachs full of arthropods, although only in one specimen did the volume of prey fully distend the stomach wall. The prey of two individuals included millipedes; two had eaten ants, two had eaten beetles, and two had eaten orthopterans. The large female also had eaten two large pieces of plant matter, presumably swallowed accidentally. There was no gross difference in prey size among the frogs in spite of their disparate sizes.

SUMMARY

Platymantis vitianus is not restricted to heavily canopied forest streams, but occurs in disturbed habitats with incomplete canopies and distantly removed from permanent streams. In such circumstances, the frogs live beneath vegetative litter and, if uncovered, attempt to escape by burrowing deeper in the litter. *P. vitianus* occurs microsympatrically with the introduced *Bufo marinus*.

ACKNOWLEDGMENTS

Field work in Fiji was made possible by The Max and Victoria Dreyfus Foundation and the Smithsonian Scholarly Studies Program. The School of Natural Resources, The University of the South Pacific, provided laboratory facilities. W. R. Heyer reviewed an early draft of this manuscript. I wish to thank all of the above for their generous assistance.

Table 1. Body dimensions of recently captured *Platymantis vitianus* from the Levuka area of Ovalua. All weights are in grams and measurements in millimeters.

NATURE PRINTS
BY DAVID M. DENNIS

We are pleased to offer four exquisite, full-color art prints by David M. Dennis, naturalist and professional scientific illustrator renown for his watercolors of unusual wildlife.

Plate 1: *Green Frog and Damselfly*
Plate 2: *Painted Turtle and Dragonfly*
Plate 3: *Spotted Salamanders in Courtship*
Plate 4: *Red Salamander and Hercules Beetle*

Prints measure 20 x 24 inches (51 x 61 cm), each signed and numbered by Mr. Dennis in editions limited to only 500 copies. $30 each or $95 for set of four prints plus shipping ($4.50) and any New York taxes.

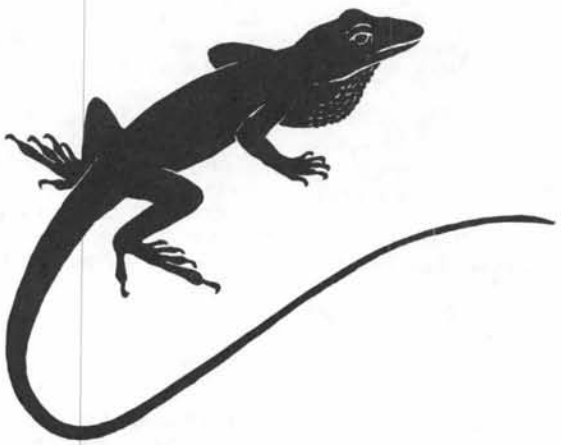
Send orders to BIOGRAPHICS, 12 Eagles Head Road, Ithaca, NY 14850. Color brochure published in *Herpetological Review* (March 1983 issue) and *Wildlife Publications Review* (June 1983 issue), or available on request from BIOGRAPHICS.

TRAUMA-INDUCED DEVELOPMENTAL VERTEBRAL DISPLACEMENT (RHOECOSIS) IN A GARTER SNAKE

ABSTRACT A case is reported for the Great Plains Garter snake, *Thamnophis radix haydeni*, of acute kypholordosis and scoliosis resulting from partial displacement of the vertebral column opposite the 54th ventral, causing injury to the spinal cord and ensuing traumatic partial amyoplasia. It is the most acute case of its kind ever recorded in snakes, the only one not of congenital origin, and only the second one not promptly lethal. The literature on the subject is reviewed for vertebrates in general, and the term rhoecosis is proposed to embrace all kinds of vertebral displacement.

Key words: rhoecosis, kyphosis, lordosis, scoliosis, snakes.

Vertebrates of several classes have been reported to show anomalous distortions of the vertebral column. In general they take three different forms. Displacement in a sagittal plane, especially dorsad and hence usually thoracic, is regarded as kyphosis (humpback); if it is ventrad, hence usually in the lumbar or cervical regions, it is designated as lordosis (sway back). Displacement in a frontal plane, to either side, is scoliosis (lateral curvature). All conditions may occur to different extents within the same animal. We here report a nearly mature snake exhibiting spontaneous occurrence of all three conditions.



No generic term exists to embrace all kinds of distortion of the vertebral column. We propose the term "rhoecosis" (from the Greek "rhoikos," meaning crooked) to serve in that context.

In mammals many cases of all three kinds of rhoecosis listed above have been documented, with disease, trauma, degenerative or genetic conditions listed as primary causes although many cases are regarded as idiopathic. A BIOSIS search through Biological Abstracts from 1969 through 1981 reveals 611 references to mammalian rhoecoses, covering experimental as well as spontaneous occurrences. Much of the former concerns hormonally-controlled behavioral lordosis in rodents (e.g. DeBold and Whalen, 1975), but considerable experimental work has been done on other aspects of anomalous vertebral columns in various mammals (e.g. Canadell et al., 1978; Spencer and Zorab, 1976). Numerous descriptions exist of spontaneous occurrences in horses (e.g. Jeffcott, 1980) and other domesticated animals, and in humans (e.g. Swank et al., 1981; Winter et al., 1979).

The same search, over the same time-span, revealed far fewer works on rhoecosis in other classes of vertebrates, with 24 on birds (e.g. McCarrey et al., 1981; Rigdon, 1971;

Riggins et al., 1977; Wise, 1977); 33 on fishes, (e.g. Austin and Hickey, 1973; Couch et al., 1977; Dorfman, 1972; Kroger and Guthrie, 1971; Moore and Burton, 1975); two on amphibians (Browder, 1972; Hadeen, 1976; both concern anurans); and four on reptiles.

The literature on reptiles is limited to turtles, lizards and snakes. Plymale et al. (1978) summarize the rather extensive literature on turtles, to which we add White and Murphy (1972). Grogan (1976) notes two records in the literature on lizards *(Agama* and *Lacerta),* and adds one record of his own *(Agama).* Although Grogan (op. cit.) states that "scoliosis is evidently a well known phenomenon in snakes," we find but one explicit record (Progscha and Lehmann, 1970), for *Sanzinia madagascariensis,* in which four of twelve young born in captivity exhibited scoliosis and kyphoscoliosis. Only one of those four survived more than a brief period after birth, and that one exhibited relatively mild vertebral deformities.

Hence a rhoecotic subadult Western Plains garter snake, *Thamnophis radix haydeni* (Kennicott), taken in early May, 1981, in Boulder, Colorado, is of special interest.

This specimen, alive at present writing, is a male measuring 338 mm s-v (June 22, 1981), tail 109 mm, possessing the characteristics typical of the subspecies: lateral light stripe on the 3rd and 4th scale rows, a relatively short tail, a yellow-orange vertebral stripe, a double row of alternating black spots between vertebral and lateral stripes, and a single row ventral to latter; vertical bars on lips; scales in 21 rows at neck and at midbody, ventrals 163, caudals 82, anal entire.

The anterior third of the body of this animal appears normal externally, whereas throughout the full length of the rest of the body and the tail the vertebral column is strongly sinuous, mostly in the sagittal plane. The ventral scales are spaced as is normal on the anterior third of the body, but elsewhere on the venter they are telescoped to no more than about two-thirds their normal length. The caudal scales are similarly reduced in length.

Sensory and motor functions persist throughout the body and tail, indicating that the innervation of the posterior myotomes is not interrupted completely although perhaps impaired. Also the snake demonstrates almost normal motions although the rear venter and tail are held partially rotated laterally at times and often seem to be dragged rather than participating in movement. In general the snake appears to be in good health and feeds (on earthworms) avidly.

Lateral and dorsal-ventral radiographs of this animal were taken to determine the extent of the vertebral malformations. As can be seen in Figure 1 (dorsal-ventral radiograph) the vertebral column is normal in the anterior third of the body, but at the level of the 54th ventral is sharply displaced to the right (scoliosis). Posterior to this point, as seen in Figure 2 (lateral radiograph), the entire rest of the body and tail display dramatic dorsoventral sagittal (kypholordotic) deviations.

The cause of the kypholordosis in this specimen is almost certainly due to some postembryonic trauma, at the level of the 54th ventral. The resultant vertebral displacement

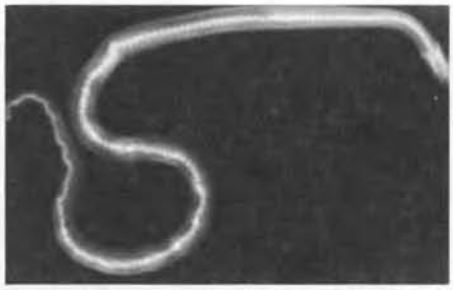

Figure 1. Dorsoventral radiograph of a rhoecotic specimen of a garter snake, *Thamnophis radix haydeni.* Total length 447 mm.

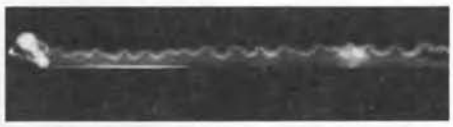

Figure 2. Lateral radiograph of the snake shown in Fig. 1. The anterior end (right) is shown only immediately in front of the site of presumed original trauma. The tail is turned toward the viewer, hence several parts appear superimposed.

presumably severely injured the spinal cord but did not sever it. The motor neurons of the ventral funiculi were probably damaged, so that the myotomes posterior to the site of injury could not develop normally, although growth was not inhibited completely. It appears that the vertebral column and other trunk organs and structures, however, continued to grow at the same rate as before, and hence became progressively more convoluted or telescoped as their size increased while the body wall remained the same or grew more slowly. In this case, then, kypholordosis and scoliosis are apparently a product of traumatic partial amyoplasia following trauma of the spinal cord.

There is only very slight evidence externally of the trauma suffered by the vertebral column; one scale in the 7th scale row opposite the 54th ventral is abnormally short, broad, smooth (lacking a keel) and fused with the diagonally adjacent posterior scale in the 6th row. The diagonally adjacent anterior scales in the 6th and 8th rows are also abnormal in having a short keel, absent on the posterior third of each scale. This small scar suggests a puncture. The site of vertebral displacement is readily evident as a bulge on the right side of the body. Elsewhere the columnar distortions are clearly apparent as middorsal bulges separated by depressions of varying length. Fourteen medial bulges are evident externally on the trunk, perhaps as many as thirteen on the tail; the latter number is uncertain because of the small sizes involved, particularly toward the tip of the tail. The terminal 20 mm of the tail has lateral as well as dorsoventral columnar displacement.

The radiographs reveal good to normal bone density with no sign of degenerative bone disease or resorption as the origin of the kypholordosis; thus trauma can almost certainly be implied as the cause of this malformation. The presence of the scar at the initial site of the disorder would appear to confirm this.

The peculiar appearance of the vertebral column throughout much, but not all, of the kypholordotic region, as though exhibiting dorsal spina bifida, is apparently an illusion resulting from a slight sinistral torsion of the body as a whole or of the vertebral column alone. Thus the vertebral column is viewed dorsolaterally in those parts rather than directly dorsoventrally, as in the anterior third of the body.The scattered hiati in the vertebral column are situated at the apices of kyphotic flexions. The only obvious anomalous vertebral osteosis lies on each side of the trauma at the 54th ventral, where two vertebrae appear to be partially fused.

Whether the condition has stabilized or will become progressively more acute as the animal grows further is unknown, but depends upon the nature of the dysfunction of the motor nerves and whether the disturbance of the myotomal growth rates was incidental or is on-going. The condition cannot be expected to diminish with time or to improve as the animal grows, except perhaps in proportion if growth rates are maintained in synchrony. The developmental damage has been done and is irreversible.

At present, the animal is being kept alive to monitor the progress of the condition. In due time the spinal cord will be sectioned to determine the histological extent of the trauma at the level of the 54th ventral, and gross dissection will be undertaken to ascertain the effect of such extensive kyphosis on the abdominal viscera and upon the myology of the body wall. In the meantime, it is evident that the kyphotic condition of this snake is a product of uncoordinated rates of growth of myotomes and the skeletal system.

In summary, this case is noteworthy especially for its susceptibility to causative diagnosis and the longevity of the subject, as well as for the extreme development of rhoecosis and the rarity of records of such anomalies among serpents. It is the only case in snakes not of congenital origin, and it is an excellent demonstration of the separate endogenous controls of growth rates of the axial skeleton and its somatic musculature.

ACKNOWLEDGMENTS

We are much indebted to Jerry Niemeyer, who found the snake and gave it to us; to Dr. Robert C. Eaton, for counsel; to Gwen Hantsbarger for radiographic assistance; and to David Fagerstrom for the BIOSIS search. The latter is available on request from the senior author.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Houston Zoological Gardens, P.O. Box 1562, Houston, Texas 77001.

CAUDATA

PLETHODON CINEREUS (Redback Salamander). **COLORATION.** An erythristic *Plethodon cinereus* was found 23 August 1977 near Raccoon Creek, Springfield Twp., Erie Co., PA. The collection site is located on the proposed U.S. Steel Lakefront Plant Site, Conneaut, Ohio.

MUSEUM OF NATURAL HISTORY The University of Kansas *Announces*

The Ecological Impact of Man on the South Florida Herpetofauna

By Larry David Wilson and Louis Porras **Co-sponsored by World Wildlife Fund - US.**

This book (*ca.* 100 pages) is a thorough account of the history of environmental degradation of southern Florida and its effect on the native amphibians and reptiles. The authors document and verify the introduction and establishment of 25 alien amphibians and reptiles into the southern portion of the state, and discredit rumors of introduced species previously thought to occur in southern Florida. Contains three maps, two of which show historical drainage patterns and the modern canal network, plus 25 black and white photographs of each of the introduced amphibians and reptiles. Eight additional photographs show aspects of alteration or manipulation of the south Florida environment.

The salamander appears to be quite similar in appearance to Reid's (1908. Am. Nat. 42:460-464) Fig. 7 of an erythristic form. The primary differences between our specimen and Reid's are that approximately 80% of the lateral and ventral surface of the tail of our specimen is black compared to only the distal half of the tail in Reid's, and our specimen has less black pigment along the lateral edges of the dorsal stripe and head. In life those regions of the body lacking melanin were a light orange color.

A second salamander captured 18 May 1977 near Raccoon Creek shows a weakly developed erythristic arrangement. In this animal there is appreciable melanin reduction on the ventro-lateral surfaces, the dorsum over the front limbs and the front limbs. In life these regions were a yellowish orange in color. There was also less melanin present on the ventral surface than expected in the normal striped form.

Erythristic forms were not found after extensive collecting along Turkey Creek, 3 km west of Raccoon Creek or near the mouth of Elk Creek, 16 km east of Raccoon Creek.

Tilley, et al. (1982. Herpetologica 38:409-417) recently summarized the distribution of the erythristic form of *Plethodon cinereus* in northeastern U.S. and Ohio. While this is apparently the first report of the erythristic phase in Pennsylvania, the collection site is only 96 km southwest of the nearest New York record (Reid and Wright, 1909. Proc. Amer. Phil. Soc. 48:370-459) and 40 km east of collection sites reported by Pfingsten (1969. J. Herpetol. 3:104-105).

The specimens were collected during the course of field work while employed by Aquatic Ecology Associates, Pittsburgh, PA. The U.S. Steel Corporation kindly granted permission for additional field work on their property. The specimens were deposited in Carnegie Museum (CM-91432, 91433).

SAURIA

CNEMIDOPHORUS GULARIS (Texas Spotted Whiptail). **HIBERNATION.** Other than reports by Trauth (1977. Herp. Review 8:33), Sellers, et al. (1980. J. Herpetol. 14:185-187), and Etheridge, et al. (1983. Copeia 1983:206-214) on the collection of large numbers of hibernating *C. sexlineatus* and by Bostic (1966. Southwest. Nat. 11:275-289) on the excavation of 25 *C. hyperythrus*, published information on hibernation in species of *Cnemidophorus* is largely anecdotal. The following describes a successful attempt to excavate hibernating *C. gularis*.

In January, 1983, Drs. J. W. Wright and J. P. Karges (Los Angeles County Museum of Natural History) expressed to me the need for hibernating *C. gularis* for research purposes. Karges suggested I search in the Lake Benbrook area south of Fort Worth, Tarrant Co., Texas. On 3 February 1983, I drove to an arbitrary site in the Rocky Creek Park area near the lake. From my past experiences in collecting *C. sexlineatus* from hibernation, I chose a moderately-sloping, SW facing embankment along a highway. Excavation began in friable soil mixed with medium to large rocks. A "swath method" was used to remove soil and rocks to a depth of ca. 30 cm in linear strips to the face of the bank. After about 15 minutes, an adult male *C. gularis* (SVL = 83 mm) was spotted in a cavity near a lodged rock. I continued excavating for ca. 1½ hrs., and my efforts yielded 7 additional lizards (SVLs = 98 mm, female; 50, 49, 46, 43, 38, and 38 mm juveniles). The juveniles were found at the ends of well-constructed burrows. Two snakes (*Sonora episcopa* and *Virginia striatula*) were also collected beneath large rocks.

I suggest that this collection technique could yield adequate samples of any species of *Cnemidophorus* from hibernation, especially when existing populations occur along highways bordered by elevated sloping embankments.

Lizards are deposited in the LACM collection, and the snakes will be deposited in the Milwaukee Public Museum.

Submitted by **STANLEY E. TRAUTH,** Department of Biology, Southern Methodist University, Dallas, Texas 75275 USA. ●

CROTAPHYTUS COLLARIS COLLARIS (Eastern Collared Lizard). **HIBERNACULA.** Legler and Fitch (1957. Copeia 1957:304-307) were the first to report observations on hibernation and nests of collared lizards. Trauth (pers. comm., 1983) found a male *C. c. collaris* (80 mm SVL) hibernation under shelf rock on 16 March 1975 in Caddo Co., Oklahoma, 3.2 km N of Anadarko off Hwy 281. The following confirms this pattern of hibernation of collared lizards.

The study site was an abandoned rock quarry located in Denton Co., Texas, 18.8 km W of Denton along U.S. 380. Four inactive adult *C. c. collaris* (two males, $\bar{x}$ SVL= 95.1 mm; two females, $\bar{x}$ SVL= 81.2 mm) were uncovered singly within hibernacula burrows on 1 March 1983 (1630 hrs; air temp = 29.4° C) beneath limestone rocks with average dimensions of 60 X 38 X 4.2 cm. All burrows were open-ended and situated nearer the largest portion of the rock chamber roof. Hibernacula dimensions averaged 12.5 X 4.8 X 5.8 cm and conformed to the body size of each lizard. Similar observations have been reported for *Cnemidophorus sexlineatus* (see Etheridge, et al., 1983. Copeia 1983:206-214) where burrow diameter correlated positively with lizard body size, suggesting that these lizards dig their own burrows and rarely utilize abandoned mammalian (i.e., rodent) shelters. The lizards were found facing head downward in hibernacula with hindquarters and tail partially exposed in a fashion similar to that reported by Legler and Fitch (1957).

Cloacal temperatures ranged from 17.2 to 18.4° C ($\bar{x}$ = 17.9 ± 0.3 SEM), while soil burrow temperatures ranged from 15.8 to 16.8° C ($\bar{x}$ = 16.2 ± 0.2 SEM). Lizards entered hibernation in mid-October 1982 and the earliest activity record was on 10 April 1983 at an air temperature of 30.6° C.

HEMIDACTYLUS GARNOTI (Indo-Pacific Gecko). **PREDATION.** *Hemidactylus garnoti* is a recent addition to the herpetofauna of southern Florida. It was reported to occur prior to 1964 (King and Krakauer, 1966. Quart. Jour. Florida Acad. Sci. 29(2):144-154). Since that time, little has been published on its interactions with other members of the south Florida faunal community. The following accounts report two cases of predation on this species.

On the morning of 2 August 1982, in a residential area of SW Miami (Dade County, Florida), a juvenile *H. garnoti* was found dead in the web of *Achaearanea tepidariorum,* the common house spider (identified by G. B. Edwards, Florida State Collection of Arthropods). When first observed, the lizard had a bloody spot near its eye, and the spider was feeding on the tail region of the lizard. Later that afternoon the tail region of the gecko appeared dehydrated, and the spider was feeding on the abdominal region of the lizard. The predation of lizards by this species of spider is an unusual occurence (G. B. Edwards, pers. comm.).

On the eve of 25 July 1982, in a residential area of Homestead (Dade County, Florida an indo-pacific gecko was observed being held by an *Osteopilus septentrionalis,* the cuban tree frog. *O. septentrionalis* is an introduced species first reported in mainland Florida in 1952 (Schwartz, 1952. Copeia 1952:117-118). The discovery of this event by the author apparently startled the frog and caused it to release the gecko, which ran off. *O. septentrionalis* has been previously reported to feed on arthropods and anurans (Carr, 1940. Univ. Florida Biol. Sci. Ser. 3(1):1-118), but not on lizards. Photographs of the predator-prey interaction of *A. tepidariorum* and *H. garnoti* were deposited with the Florida State Collection of Arthropods, Gainesville, Florida.

LAEMANCTUS LONGIPES (Casque-headed Lizard). **REPRODUCTION.** There are few accounts in the literature that refer to the eggs and hatchlings of the tropical American lizard *Laemanctus longipes* (Fitch, 1970. Univ. of Kansas Mus. Nat. Hist. Publ. (52):1-247).

A sexual pair of lizards, from an unknown locality, was obtained by the Fort Worth Zoological Park (FWZP) in October, 1980. The lizards were initially housed together in a planted exhibit measuring approximately 1 x 1.7 x 2 m. The female laid two eggs on 18 March 1981, which were incubated in a vermiculite medium (Tryon, 1975. Bull. New York Herp Soc. 11:33-37) at temperatures ranging from 26.6° C-32.2° C. The eggs hatched on 7 May 1981. The young weighed 2.3-2.4 g and measured 45-47 mm SVL, and 190-192 mm TL.

A second pair of *Laemanctus longipes,* without locality data, was obtained by FWZP on 12 March 1981. These lizards were also housed in the previously mentioned exhibit from which the first pair had been removed. The female deposited four eggs in sphagnum moss under a shallow water dish on 5 August 1982. Weights and measurements were not taken on the eggs until 30 August 1982 at which time they weighed 4.0-4.5 g ($\bar{x}$ = 4.1) and measured 16.2-17.0 mm ($\bar{x}$ = 16.4) in width and 25.3-26.4 mm ($\bar{x}$ = 25.8) in length. The eggs were incubated in a similar fashion and hatched on 29 and 30 September 1982. All of the hatchlings weighed 2.4 g and measured 43-46 ($\bar{x}$ = 45.2) mm SVL and 181-188 ($\bar{x}$ = 182.7) mm TL. On 30 September 1982, the adult female weighed 31.8 g and measured 124 mm SVL and 509 mm TL and the adult male weighed 31.0 g and measured 106 mm SVL and 498 TL.

Coloration of all hatchlings resembled that of the parents.

SERPENTES

CALLOSELASMA RHODOSTOMA (Malayan pit viper). **FOOD.** The natural diet of *Calloselasma rhodostoma* has been listed as rats, frogs and lizards (Lim, 1956. Malayan Nature Journal 10:139-144). Recent observations at the Fort Worth Zoological Park (FWZP) show that captive hatchlings will accept a wider ranging diet, which includes toads, fish, and snakes of their own species.

A clutch of nine eggs hatched at FWZP on 21 May 1981. Six of the young were retained and housed individually in gallon jars. On 30 July 1981 recently metamorphosed toads *(Bufo woodhousei)* were accepted by all of the snakes and on 16 December 1981, four of the six young consumed golden shiners *(Notemigonus crysoleucas).*

An instance of cannibalism in a pair of young snakes was noted at FWZP on 7 September 1981. The snakes hatched from a clutch of 25 eggs on 5 July 1981 and were initially housed separately in gallon jars. A number of small frogs *(Acris crepitans)* had been accepted by both snakes before they were housed together which was approximately one week prior to cannibalism.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **COLORATION.** On 3 August 1980, an albino rattlesnake was collected by Mrs. Lloyd Lewis on a wheat farm near Follett, Lipscomb Co., Texas. The specimen is a juvenile male (293 mm SVL), possessing one rattle and a button. The skin is basically leucistic with a faint, light tan dorsal stripe. The specimen was identified as *Crotalus viridis viridis,* based on scutellation, by T. L. James and F. C. Killebrew.

This individual was received alive on 10 August 1980 and observed in the laboratory until its death on 30 September 1980. The specimen was lethargic and rejected all food that it was offered. The specimen was preserved and deposited in the West Texas State University Museum of Natural History (WTSU 7578).

L. M. Klauber (1956, Rattlesnakes; Their habits, life histories, and influence on mankind. Berkeley, Univ. California Press, Vol. 1, pp. 231-234) noted that the approximate rate of albinism in natural populations is only 0.1% to .01% and that albinos have a low survival rate past the juvenile stage due to the effects of competition and predation. Klauber (op. cit.) also noted the locations of several reported cases of albinism in the prairie rattlesnake. Other reported specimens of albinistic prairie rattlesnakes are summarized by Stanley Dyrkacz (1981, SSAR Herpetological Circular No. 11, pp. 1-31). No other albinistic specimens have been noted in the collecting locality of our specimen. The closest recorded specimen was reported from a locality approximately 450 km NE of our site at Scott County Park in Kansas (R. J. Boles, 1971, Alabaster, Kansas School Natur. 17(3):3-15).

LAMPROPELTIS CALLIGASTER CALLIGASTER (Prairie Kingsnake). **PREDATION.** Prairie kingsnakes prey upon a wide variety of food items (Klimstra, 1959. Herpetologica 15:1-5) with reptiles (mostly snakes) constituting only a small portion (6.8% by volume) of its diet. Lizards, such as *Sceloporus undulatus* (Klimstra, op. cit.) and *Cnemidophorus sexlineatus* (Burt, 1935. Amer. Midl. Nat. 16:311-366; Webb, 1970. Reptiles of Oklahoma), are also consumed. The following is an account of a predator-prey encounter between *L. c. calligaster* and *C. s. viridis.*

On 14 June 1978 in Huges Co., Oklahoma (ca. 3 km E Calvin), I observed an adult male *C. s. viridis* (SVL = 67 mm) moving cautiously along the base of a sandy, red-clay roadcut. Since numerous activity burrows of the lizard species were present, I decided to wait and see if the lizard would enter one, and then dig it out. As I moved closer, I saw a juvenile female *L. c. calligaster* (SVL = 350 mm) ca. 1.5 m away from the lizard. She was slowly weaving around clumps of soil, occasionally poking her head into an entrance of an activity burrow. Soon, she sighted the lizard and, immediately, chased it into a burrow. I removed the snake (over half of its body was inside the burrow) and then dug out the lizard.

Both specimens (SET 2842 and 2825) will be deposited in the Milwaukee Public Museum.

NERODIA ERYTHROGASTER FLAVIGASTER Yellowbelly Water Snake). **COLORATION.** A young female amelanistic specimen of *Nerodia erythrogaster flavigaster* was collected in Harris County, Texas, in the Pasadena city limits near the east border of South Houston. The snake, collected by Sue Ezell, was found crawling among weeds in a drainage ditch on 25 September 1982. Its ground color is a light flesh tone bordered by cream-colored bands that surround the dark tan blotches on its back. The sides are marked with chocolate-brown spots which are also encircled with cream-colored rings. The eyes are bright red and the head is pinkish-orange. The last few inches of the tail are bright orange (Fig. 1).

At the time of its capture the snake measured 440 mm total length. Since that time it has fed on a diet of small goldfish. Upon its death the snake will be deposited in the vertebrate collection of the Carnegie Museum of Natural History.

Figure 1. A young amelanistic *Nerodia erythrogaster flavigaster* collected in Harris County, Texas, in September 1982. Photo by Mara Freed.

THAMNOPHIS PROXIMUS PROXIMUS (Western Ribbon Snake). **FOOD.** Western Ribbon Snake *(Thamnophis proximus proximus)* has been reported to take a broad range of prey items. Fouquette (1954. Texas J. Sci. 6:172-188) provided a summary of food habits from Texas specimens and Rossman (1963. Bull. Florida State Mus. 7:99-178) surveyed the literature on the *sauritus* group of the genus. Clark (1974. Herpetologica 30:372-379) reported on the food habits of a Texas population.

All of these accounts reported a wide range of prey items consumed by this species. Amphibians, both metamorphosed and larval, especially anurans, are the major component of the diet of this species. Toads of several species have occasionally been reported in the diet of *T. p. proximus.*

At ca. 2400 hrs, 10 July 1982, while "road-cruising" for amphibians along County Rd. H, west of Englewood, southeastern Boone County, Missouri, after a moderately heavy rain, I observed a ribbon snake thrashing on the road surface. I stopped, assuming the snake to be injured, but on approach I discovered a large (ca. 70 cm TL), uninjured *T. p. proximus.* The thrashing was an apparent attempt to dislodge a badly smashed and partially dried toad (either *Bufo americanus* or *B. woodhousei*), ca. 6.0 cm SVL, from the pavement to which it was adhered. The snake had the distal portion of the left hind limb of the toad in its mouth and was violently thrashing its body from side to side in a whiplike motion. The snake continued this behavior as I approached to within 0.5 meters. I observed long enough to identify the snake and attempted to identify the toad, then backed away to avoid disturbing the snake. I left and returned approximately 30 min later. The snake and the toad were gone, suggesting that the snake had succeeded in its scavenging.

The night was typical of rainy July nights in central Missouri, with nothing unusual that might explain the behavior of the snake. The week preceding the event had been rainy, as had much of the summer (NWS, Columbia Regional Airport) and amphibians were active and abundant in the area at the time, thus eliminating prey scarcity as a factor.

The scavenging of road-killed animals has not been previously reported for this species and is unusual because of the ready availability of alternate prey items, both alive and more freshly dead, the condition of the toad, and amount of effort needed to dislodge it from the pavement.

TESTUDINES

CLEMMYS GUTTATA (Spotted Turtle). **X** ***CLEMMYS MUHLENBERGII*** (Bog Turtle). **NATURAL HYBRID.** No hybridization has been previously reported in the North American turtles of the genus *Clemmys.*

In April 1979, a resident of Baltimore County, Maryland found a female bog turtle, *Clemmys muhlenbergii,* in a shallow brook on his property where both bog turtles and spotted turtles, *Clemmys guttata,* occur. The female was kept until June when she laid two eggs and was then released at the capture site. The eggs were incubated, but only one developed and hatched. The hatchling was kept until the summer of 1982 when it was given to one of my former students. Unfortunately it developed a severe mycotic infection, and was in poor condition when brought to me in November, 1982. Despite treatment it died in January 1983, and has been preserved in the George Mason University herpetological collection (GMU 1452).

The juvenile female (carapace 76.0 mm, plastron 69.2 mm) is clearly a hybrid between *C. guttata* and *C. muhlenbergii.* It most closely resembles *C. guttata* in coloration and patterns, but *C. muhlenbergii* in shell morphology. The carapace is blue-black with scattered small yellow spots as in *C. guttata.* However, it contains a dorsal, medial keel from the posterior third of the first vertebral scute to the anterior third of the fifth vertebral; such a keel occurs on *C. muhlenbergii,* but never on *C. guttata.* The carapace is also more domed, has a slightly serrated posterior rim, and shows prevalent growth annuli on each carapacial scute, all characters associated with *C. muhlenbergii,* but not *C. guttata.* The coloration and pattern of the plastron are as in *C. guttata,* as is also a very shallow posterior notch. The head is dorsally blue-black with a few yellow spots, typical of *C. guttata,* but the tympanic area contains a large, broad, rounded, orange blotch, as in *C. muhlenbergii;* this spot in *C. guttata* is elongated, narrow and yellow. The jaws, chin and iris show the typical sexual dichromatism of female *C. guttata,* and the limbs are also colored and patterned as in *C. guttata.*

GOPHERUS POLYPHEMUS (Gopher Tortoise). **SCUTELLATION.** At 1015 hours on 1 June 1981 an adult *G. polyphemus* (carapace length 250 mm, mass 4.7 kg) was observed in the process of egg deposition. The nest site selected by this female was a construction area that had been built up with fill dirt. This individual was a member of a free ranging population of *G. polyphemus* at Santa Fe Community College Teaching Zoo (4.5 ha), Gainesville, Florida.

On 4 September 1981 following a 95 day incubation period, 6 hatchlings emerged from the nest. All hatchlings exhibited aberrant scutellation of the carapace (Fig. 1, page 76). Measurements (McCrae, et al. 1981. Herpetologica 37(1):46-52) of the 6 hatchlings were as follows: mass 32.0-36.8 g, mean 33.9 g; carapace length 47-49 mm, mean 48.5 mm; total length 52-54 mm, mean 53 mm; carapace width 42-44 mm, mean 43.3 mm; maximum thickness 27-29 mm, mean 28.0 mm; plastron length 49-52 mm, mean 49.6 mm; anal notch 7-9 mm, mean 7.5 mm; anal width 9-11 mm, mean 9.5 mm. Further excavation of the nest site revealed 2 fertile but undeveloped eggs (41 x 46 mm, mass 41.5 g; 41 x 44 mm, mass 41.1 g) at the bottom of the nest.

In 1982 the same female was monitored nesting at a site where clay and fill dirt had been deposited. After 120 days the nest site was excavated. One live tortoise (UF 53441) was removed from the egg which exhibited aberrant vertebral scutellation. Examination

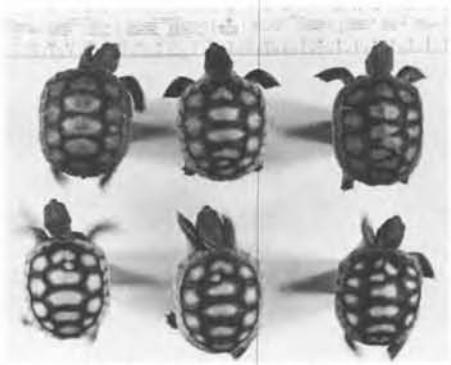

Figure 1. *Gopherus polyphemus* clutch exhibiting epidermal scute anomalies of the carapace. Photo by Andrew Manis.

of the remaining clutch was inconclusive due to previous nest destruction by ants and Diptera larvae.

Scute abnormalities can occur with some frequency in wild populations (Douglass, 1977. Florida Sci. 40(3):256-258). If the abnormalities noted above were the result of embryonic stress, insufficient water in the egg environment may have been a contributing factor (Lynn and Ullrich, 1950. Experimental production of shell abnormalities in turtles. Copeia 1950:253-262). This circumstance is more likely to occur when females choose to nest in areas altered by man.

Upon death the specimens noted above will be deposited in the vertebrate collection of the Florida State Museum.

MALACLEMYS TERRAPIN TERRAPIN (Diamondback Terrapin). **NESTING.** This note reveals nesting of a Diamondback Terrapin population in the Hackensack River salt marshes, meadows of Lyndhurst, New Jersey. According to the literature (Pope, 1971, Turtles of the United States and Canada, Alfred A. Knopf, Inc., pp. 156-157; Conant, 175, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., pp. 52-53), *M. terrapin* prefers quiet unpolluted estuaries. Considering that this area has been heavily industrialized and is under active commercial development, these observations are of interest.

Active nests were observed from 1980 to 1982. Eggs were collected and incubated at ambient room temperature to determine emergence time and to verify species. Hatchlings were released at original nest sites. In mid-July, 1980, four *M. terrapin* nests were discovered approximately 12 ft. from the water in the Lyndhurst meadows area (Lyndhurst site). The nests contained 8, 9, 12 and 17 eggs respectively. These nests were on the top of an exposed clay mound located at the end of a brackish channel. *Phragmites* spp. was the dominant vegetation. Emergence was on the 18th, 22nd and 31st of August and 12th of September.

In August 1981, at North Arlington, New Jersey (two miles west of the Lyndhurst site), in the same salt marsh system, a trampled *M. terrapin* nest was discovered. It was located on a well-used foot path in sandy clay soil approximately 30 ft. from water's edge on level open ground. The nest site soil and the unhatched eggs were severely compressed by people walking the path. The dead, unhatched turtles appeared to be fully developed. The Lyndhurst site also had two *M. terrapin* nests in mid-June, 1981, located on the same clay mound. The nests contained 8 and 12 eggs, with emergence on the 11th and 17th of August 1981.

A third site was found in August 1982 on the bank of the Hackensack River, near East Rutherford, New Jersey (three miles northeast of the Lyndhurst site). A single nest was on the slope of an open sandy mound (approximately 70 ft. from the water), surrounded by *Phragmites* spp. The nest contained 17 eggs; emergence was on the 20th of August. In 1982, two nests were also found at the Lyndhurst site. These two nests contained 14 and 16 eggs which hatched on the 9th of August and 1st of September 1982.

In summary, ten *M. terrapin* nests were located at three different sites in New Jersey's Hackensack Meadowlands from 1980 through 1982. Nests were in tidal river or salt marsh habitat, with *Phragmites* spp. being the predominant vegetation. The finding of *M. terrapin* nesting activity in the New Jersey Meadowlands suggest that, during this period, water quality and habitat were adequate to support a population of these turtles.

STERNOTHERUS ODORATUS (Stinkpot). **ALGAL RELATIONSHIPS.** On 9 April 1983 a male *Sternotherus odoratus* was collected from President's Pond, Jackson County, Illinois, and brought into the lab. It was found moving along the bottom of the pond in 30 cm of clear water and was well camouflaged by a dense covering of algae on its carapace. Its carapace measured 10.5 cm and the algae was 17 cm deep. The algae was predominantly *Basicladium chelonum* that is normally epizoophytic on turtles and the plastron was covered with the branching protozoan commensal *Opercularia* to a depth of 3 mm.

The next day the stinkpot was observed eating the algae off of its carapace. By the following day it had eaten all the algae within reach of its mouth leaving a cropped area on either side of its carapace.

The algal-turtle relationship has generally been accepted to be one of mutualism. Epizoic algae profit by gaining mobility and protection from the turtle as well as being freed from most competition for substrate with other algae. The turtle in turn is camouflaged from predators and prey by the epizoophytic algae which may even attract potential prey. Algal growth has been shown to harm or even cause the death of turtles. The ingestion of the algae by the turtle puts a new twist into their symbiotic relationship. A relationship where the turtle occasionally eats the algae and the algae occasionally harms the turtle can not be considered completely mutualistic.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

EFFECTS OF ROTATION ON THE VIABILITY OF TURTLE EGGS

There are abundant warnings in the literature on the dangers of disturbing the orientation of turtle eggs. Ewert (1979), Pritchard (1979), Tracey et al. (1978) and Tryon (1978) have all cautioned that an increased mortality rate will result if turtle eggs are disturbed. However, all of these observations were of a subjective nature without quantitative data to substantiate them. Bustard (1972) and Limpus et al. (1979) both concluded that there's an increased mortality in sea turtle eggs that are moved during certain periods of incubation. Limpus' work required the construction of man-made nests which introduced an uncontrolled variable into the experiment. Since Burger (1976) has shown that subtle variations in nest location can radically alter egg mortality Limpus' data must be interpreted carefully. Drajeske (1974) and Marcellini (1982) both have reported controlled experiments involving small numbers of turtle eggs that result in no increase in mortality from egg manipulation. In this paper large numbers of eggs of *Malaclemys terrapin*, *Chelydra serpentina* and *Chrysemys picta picta* were rotated at various intervals under controlled conditions to determine if such motion did increase egg mortality.

Table 1. Hatching rates of rotated and control eggs of *Malaclemys T. terrapin.*

Materials and Methods

All eggs used in this study were collected from fresh nests and marked to maintain orientation. Thirteen *Chrysemys*, 13 *Malaclemys* and 4 *Chelydra* nests were used in the study. All eggs were randomly assigned to the control or one of the rotated groups. All rotated eggs were turned 180° once during development (from top to bottom).

All eggs were incubated in a mixture of 600 g vermiculite and 670 cc water in plastic, transparent sweater boxes. Eggs were half buried in the mixture. The temperature of the nest boxes varied with the room. Highest temperature recorded was 38° C and the lowest was 20° C. Water was added to the vermiculite as it was needed to maintain egg volume. Average time to hatching was 58 days.

In the first year of the study the eggs of all three species were turned after one, two, three, four, five, six, or seven weeks of incubation. No egg was turned more than once. Eggs in the control group were not disturbed. A total of 284 eggs was used the first year.

In the second year eggs of *Chelydra serpentina* were rotated on day one, three, six or nine. These eggs were also rotated only once. Control eggs were undisturbed. Seventy-one eggs were used. The purpose of the second year's study was to evaluate the possible increased mortality of *Chelydra* eggs rotated in the first week of incubation. All hatchlings were kept at least two weeks after hatching. No mortality was observed.

Results

As tables one, two and three show there was very little difference between the success rate of rotated and control eggs. The only possible exception was the 50% mortality of *Chelydra serpentina* eggs turned after one week's incubation (Table 3). Table 4 illustrates the results of an experiment designed to further assess the effect of rotation during this first week of incubation for *Chelydra serpentina*. Results clearly show that there was no increase in mortality with rotation of these eggs.

This study shows that eggs rotated under the stated conditions hatch with about the same success as undisturbed eggs, for the three species evaluated.

REPRODUCTION IN TWO SPECIES OF CAPTIVE BROWN SNAKES, GENUS *Pseudonaja*

The genus *Pseudonaja*, comprised of six currently-recognized species, is found throughout mainland Australia with one species, *P. textilis*, also occurring in eastern Papua (Cogger, 1979). All are venomous and four are considered dangerous (*P. affinis, P. guttata, P. nuchalis* and *P. textilis*) (Sutherland, 1981).

Within Australia, brown snakes are maintained in greater number and diversity by private collectors than by zoological institutions. However, relatively little information concerning their reproduction in captivity has been published.

The Royal Melbourne Zoo has included the Eastern brown snake (*P. textilis*) in its reptile collection for many years but has maintained Western brown snakes (*P. nuchalis*) since 1973. Since detailed records of the collection have been kept, *P. nuchalis* has been bred twice and *P. textilis* on three occasions.

Materials and Methods

Due to their small size and initially nervous temperament, the two original *P. nuchalis* were housed separately in off-limit tanks. These cages were quite spartan, with gravel on the floor, a 'hide-box' for cover and a small water bowl. Temperatures varied from 25-32° C. Both snakes fed well on dead mice, often seized the first mouse vigorously and sometimes used their bodies to hold the mouse against the side of the tank. Gillam (1979) noted similar methods of prey restraint for a number of *Pseudonaja* species including *P. nuchalis*.

In early March 1980, both snakes were transferred to a 1 m x 1 m x 1 m exhibit containing a thick layer of gravel on the floor as well as a small pond and a section of tree stump. The snakes often attempted to burrow beneath the stump, necessitating daily attention to the display. Gillam (1979) noted that in the Northern Territory, this species often uses lizard and mammal burrows as shelter.

The adult *P. textilis* were displayed in the same exhibit following removal of the *P. nuchalis*.

Newly-laid eggs were weighed on a triple-beam balance, measured with calipers and placed in vermiculite-filled containers (Table 1). The young snakes were also weighed on a triple-beam balance and were measured using the squeeze-box technique (Quinn and Jones, 1974) within two days of hatching.

P. nuchalis

The Western brown snake is found Australia-wide except for a narrow strip extending the length of the eastern coast and reaching into South Australia. Highly variable in colour and pattern, it is basically light brown to russet or black above with irregular, darker bands or small marks, particularly about the head and nape. The belly varies from cream to orange or gray with darker blotches (Cogger, 1979).

The original (Melbourne Zoo) male was received from the Renmark area in South

Australia on 9 April 1973, as a 4-5 month old juvenile of 350 mm total length. At this time of writing, the snake measures 1.66 m snout-vent and 1.79 m total length.

The original female arrived on 4 February 1974 from southern Western Australia. This was a larger snake, probably 12-15 months of age. The two snakes were similar in coloration but possessed different neck markings.

Breeding

The adult snakes were first placed together in an off-limit tank in early December 1976. They were left together until the following April but no courtship or mating behaviour was observed, although the male exhibited nervous behaviour in the presence of the female. They were placed together again for five days in mid-September, but again there was no sexual activity. However, when the male was retrurned to the female on 3 October, immediately after she had sloughed, mating was observed. This was repeated on the following day and the male was removed on 7 October. The female laid nine eggs from 17 November-9 December. These were all fertile as tiny embryos were clearly visible, but unfortunately they were premature, with the final layer of egg shell apparently absent. The eggs were not incubated.

A similar sequence of events occurred during 1978 and 1979. The snakes were placed together in early October immediately following the female sloughing, mating occurred the next day, and the male was removed after 3-6 days. Oviposition occurred in early December. The female also laid a clutch of eight fertile eggs in late February 1978. Both snakes appeared to become agitated for short periods when together. This appeared to be initiated by the female when the male's body came into contact with hers. She whipped her tail violently from side to side and moved rapidly around the tank, which caused the male to react in a similar manner. After 5-10 minutes they resumed normal activity. This was initially thought to be a male/female interaction but in recent months similar behaviour has been observed between two young males. In 1978, 17 eggs were laid, of which two were infertile and were not incubated. Another egg was removed during incubation when it became mouldy. By day 53 the eggs had increased in size by an average of 3 mm (width).

Hatching occurred over five days commencing 2 February with the resultant incubation period being 59-64 days at an incubation temperature of 28° C. A total of 15 snakes emerged including two from one egg. These appeared normal apart from lacking eyes. Seven other snakes lacked one eye.

The 1979 clutch consisted of 12 eggs of which only one was fertile. This egg hatched after an incubation period of 52 days at 30° C.

The first slough occurred after 10 days and some individuals became extremely aggressive, striking without hesitation when disturbed. Initially the young snakes had pale brown/orange bodies, black heads and two narrow black bands on the nape. After one month the black markings had changed to a dark brownish-orange and by the end of the first year, the head had assumed the same tan color as the body. By this time the nape bands had also diminished to a single diagonal bar of 4-6 black scales as well as 2-4 separate black scales. Ventral coloration had changed from a pale cream with orange flecks at hatching to pale yellow with gray/brown flecks. The young of both clutches showed similar alterations in color and markings. The slightly 'speckled' appearance of the adults began to show after about eight months of age.

The young snakes were fed only on pink mice. Some accepted these quite readily but the majority had to be tricked into taking mice after the latter had been rubbed with the body of a frozen skink. After some months the snakes began to accept untreated mice and grew steadily (Table 2). The two remaining snakes were sexed by probing on 14 May 1982 with the following results:

Male 2 (3 years, 3 months) - probe depth of 48 mm; 14 sub-caudals.
Male 3 (2 years, 4 months) - probe depth of 48 mm; 15 sub-caudals.

P. textilis

The Eastern brown snake is found in a wide range of habitats throughout eastern Australia. Adults are usually a uniform brown although a wide range of different shades occurs. The belly is cream to orange with scattered orange or grayish flecks (Cogger, 1979).

Table 1. Egg data at oviposition for *P. nuchalis* and *P. textilis* at the Royal Melbourne Zoo.

Species	Clutch	Clutch size (Nos. fertile)	Mean egg length(mm)	Mean egg width(mm)	Mean egg weight(g)
P. nuchalis	17 Nov-9 Dec 1977	9(9)	Eggs	premature

Table 3. Summary of reproductive data for *P. nuchalis* and *P. textilis* at the Royal Melbourne Zoo.

	P. nuchalis	*P. textilis*
Time of mating	3-10 October	28 September-12 October (1972 & 1977 only)
Time of oviposition	17 November-9 December	29 October-5 December, 21 December from 1971 wild mating.
Gestation period	45-67 days	52-56 days (1972 & 1977 only)
Incubation length	52 days (at 30° C) 59-64 days (at 28° C)	40-42 days (at 30-31° C) 49-52 days (at 28° C)
Clutch size	9-17 (mean 12.3, n = 3)	8-28 (mean 14, n = 5)

Breeding

The first recorded reproductive event for this species was the laying of 28 eggs by a newly arrived female on 21 December 1971. Although nine were fertile, none hatched.

Copulation involving a second female was observed on 12 October 1972. This snake had been in the collection for at least three years. The male was donated in 1971. After constructing a shallow depression the female laid 14 eggs on 5 December. Six of these were infertile but the remaining eight produced young snakes which hatched after 49-52 days incubation at 28° C.

A pair of *P. textilis* hatched in 1973 were placed on display on 27 September 1977 in the exhibit described for *P. nuchalis*. Mating was noted on the two following days and 10 eggs were laid 56 days later on 23 November. The two snakes remained together until the female's death on 29 January 1980 at an age of seven years. Attempted or successful copulation was observed on 19-20 February, 30 March, 2-10 May, 9 August, 26-28 September, 10-12 and 23-28 October and 3 November in 1978; and 24 April, 2 August and 3 September in 1979. Mating was also seen following oviposition on 3 November 1979. On this occasion the male had been removed from the female two days prior to laying, and reintroduced on 1 November.

On 23 November 1978, five fertile eggs were found at the rear of the exhibit. These were severely dehydrated and were thought to have been laid at least ten days earlier. A further four eggs were laid on 17 December and although one was fertile, it failed to hatch. In 1979 the female started to fill out in early October and refused to feed. Nest material was provided on 27 October and eight eggs were deposited on 29 October. These were rather elongated and blood vessels were visible in three eggs.

As with the *P. nuchalis*, the eggs were laid 12-13 days after the female sloughed. In 1977, eight young hatched after an incubation period of 40-42 days at 30° C. The remaining two eggs were infertile. Of the eight eggs laid in 1979, only three were fertile. Two hatched after an incubation period of 41-43 days at 31° C but one young snake had a severely kinked spine and died 19 days after hatching. The remaining egg contained an almost full-term dead embryo which did not appear to be malformed.

The first slough occurred after 8-9 days. The young of neither clutch were as aggressive as the young *P. nuchalis* and all possessed only a single, black band on the nape as well as a black head. They were all a brownish-orange dorsally and a pale orange with brown spots on the ventrals. Although their markings faded with age, none remained in the collection long enough for us to witness the complete disappearance of the black head and nape markings. Great difficulty was experienced in persuading the young snakes to accept small mice despite using the methods described earlier for the young *P. nuchalis*. Long-term growth data were not obtained.

Discussion

A summary of reproductive data for the two species is shown in Table 3. As there are few published reproductive data for these species, under either wild or captive condition, it may be of value to make observations based on the data presented here, despite the relatively small sample size.

The species are similar in the timing of mating and oviposition; gestation period and mean clutch size. Worrell (1970) stated that in *P. textilis* mating takes place during October and November with egg-laying following in December and January. Shine (1977 a & b) found that females of both species in the New England region of New South Wales 'ovulated late spring (November) . . . . . and oviposited shortly thereafter.' The specimens in this study followed a similar pattern and the continued interest shown by the male *P. textilis* in the female may have simply been a result of captive conditions. The continued presence of the male *P. textilis* might also have led to a stressful situation for the female as neither 1978 or 1979 were successful years.

If the first, possibly premature, clutch deposited by the female *P. nuchalis* is discarded, the number of eggs per clutch decreased for both species as the females increased in age and size. This is not a normal occurrence (Fitch, 1970) and may again be related to captive conditions, although we have found the reverse to occur in another oviparous Australian elapid, *Oxyuranus scutellatus*, housed in similar conditions (Banks, in press). There are insufficient data to establish whether smaller clutches consisted of larger eggs.

In general, clutch sizes in this study are similar to those previously recorded for both *P. nuchalis* (Gillam, 1979; Gow, 1976) and *P. textilis* (Gow, 1976; Wells 1980; Worrell, 1970). The incubation length was shorter for *P. textilis* than for *P. nuchalis* at the same incubation temperatures. The only other record of captive incubation is 74 days at 24-30° C for a clutch of 11 *P. textilis* eggs (Wells, 1980). *P. nuchalis* is generally found in areas of consistently higher temperatures than *P. textilis* and it is possible that individuals of the latter species from Victoria and southern New South Wales, where seasonal temperatures are unpredictable, have adapted to take advantage of shorter periods of temperatures which are suitable for successful egg incubation.

Newly-laid eggs and newly-hatched young of *P. textilis* were smaller and weighed less than those of *P. nuchalis*, except that the mean hatchling weight was slightly greater for *P. textilis*. Wells (1980) found that seven hatchling *P. textilis* measured 235-300 mm total length (mean 275 mm) and weighed 4.71-7.20 g (mean 6.10 g); slightly less than for the individuals in this study.

In the five instances where hatching occurred, twice for *P. nuchalis* and on three occasions for *P. textilis* (see Table 2), two of the groups of hatchlings contained malformed individuals. For *P. nuchalis*, of the 15 snakes emerging from 14 fertile eggs incubated at 28° C, eight were malformed. In contrast, one normal snake emerged from the single, fertile egg incubated at 30° C. For *P. textilis*, eight normal snakes hatched from eggs incubated at both 28° C and 30° C; whereas only one normal snake hatched from three fertile eggs incubated at 31° C. One hatchling was severely malformed and the remaining individual died in the egg.

Poor hatching rates and hatchling deformities in reptiles resulting from excessively high incubation temperatures have been reported by a number of workers (Dunn, 1981; Ross, 1980; Zweifel, 1980). Incubation temperatures which are too low have also been reported to cause hatchling deformities in *Crocodylus porosus* (R. W. Dunn, pers. comm.). It is possible that incorrect incubation temperatures led to the malformations noted here. If that is the case, it appears that 28° C is too low for eggs of *P. nuchalis* and 31° C is too high for *P. textilis* eggs. Further study is required to determine exact ranges for successful incubation of eggs from these species.

TECHNIQUES

A NITROCELLULOSE EMBEDDING TECHNIQUE FOR VERTEBRATE MORPHOLOGISTS

INTRODUCTION

Herpetologists preparing material for light microscopy may have difficulty finding histological techniques that provide faithful representation of the many tissue types they wish to examine. I describe a low-viscosity nitrocellulose (LVN) embedding procedure useful to morphologists who encounter such problems. LVN has been primarily used in this lab in the preparation of heads and soft tissue of members of the order Gymnophiona for comparative morphological studies. Caecilian heads are very bony and can be difficult to section. A variety of decalcification, dehydration and embedding schedules and techniques were tried and the following protocol was selected as providing the best mixed tissue integrity for these and other specimens.

In addition to ease of preparation LVN has several advantages over other embedding media. No heat or pressure is used during infiltration as is used with paraffin. The minimal tissue perturbation curtails shrinkage and results in sections with tissue relationships more accurately maintained. In addition LVN provides greater support so that larger tissue blocks can be satisfactorily sectioned. Differential staining is brighter and more distinct than with the epoxy plastics and with less wrinkling of sections. The tissue blocks are relatively soft, facilitating cutting and the maintenance of knife sharpness. Seven microns is about the minimum at which sections can be cut, but much thicker sections can be cut quite easily. This is particularly useful in tracing structures through sequential sections and aids in making three-dimensional reconstructions.

PROCEDURE

The following protocol is an outline for complete tissue preparation from decalcification through staining and mounting.

LVN PREPARATION

The LVN is available from Hercules Inc., Wilmington, Delaware (RS 1/2 grade). Three solutions are made: thin, medium and thick.

Thin LVN

Absolute ethanol	112.0 ml
Anhydrous ether	168.0 ml
LVN	30.0 g

Medium LVN

Absolute ethanol	112.0 ml
Anhydrous ether	168.0 ml
LVN	60.0 g

Thick LVN

Absolute ethanol	112.0 ml
Anhydrous ether	168.0 ml
LVN	100.0 g

The LVN is shipped and should be stored in 40% alcohol. Dry it thoroughly in a large pan lightly covered with cheesecloth before weighing it out. This should be done under a hood and away from any open flame as nitrocellulose is extremely flammable. The LVN will take on a powdery appearance as it dries and should be ready for use in 1 or 2 days. Periodic stirring will speed the process. Mix the LVN and the alcohol in clean, dry, brown jars (light causes the LVN to deteriorate). Shake well to thoroughly dampen the LVN and let sit for 24 hours. Next add the anhydrous ether shaking vigorously to break up lumps. Seal the tops of the jars with waterproof tape to prevent evaporation. Rotate them top to bottom and side to side several times daily until all the LVN has gone into solution (1-2 weeks for the thick LVN). If the solutions dry out and become too thick additional anhydrous ether:absolute alcohol (A&E) in a 1:1 ratio can be added. All water must be excluded.

DECALCIFICATION AND DEHYDRATION

In decalcification the most consistently good results were obtained using Humason's (1979) Formic Acid A solution. It is not too harsh and tests for completeness of decalcification are reasonably accurate.

Formic Acid A

Formic Acid	5-25.0 ml
Formalin (concentrated)	5.0 ml
Distilled water to make	100.0 ml

Place tissue in the solution for 1-7 days depending on the size of the tissue and the amount of bony material present. To test for completion of decalcification, take 5 ml of the formic acid tissue solution and add to it 1 ml of 5% sodium oxalate. Decalcification is complete if no white precipitate forms within 5 minutes. The tissue should be put in fresh Formic Acid A after each test.

To dehydrate run the tissue through alcohols of increasing strength, timing dependent on the size and permeability of the tissue.

70%	1-6 hr
80%	1-6 hr
95%	1-6 hr
100%	1-6 hr (two changes)
A&E	1-6 hr (two changes)

INFILTRATION AND EMBEDDING

To infiltrate leave the decalcified, dehydrated tissue in a vial of thin LVN (approximately 20x volume) for several days to several weeks depending on size and type of tissue. For reference, a 15x20 mm salamander head will require 5-7 days to infiltrate. Gentle heat from a warming tray at 40° C will speed infiltration with no detrimental effects. Unsuccessful attempts were made to speed this process at higher temperatures with vacuum pressure.

Transfer the tissue to a vial of medium LVN leaving it in solution for a comparable amount of time as in the first solution. The used solutions can be saved in marked bottles and used for subsequent infiltrations.

Leave the tissue in a vial of thick LVN for the same time period as used in the two preceding steps. The tissue can be left up to a month or more at each step. This is advisable if it is very dense and sections less than 10 μ are desired.

To embed use a stender or other straight-sided glass or plastic container. Pour in fresh thick LVN and insert the tissue specimen. The tissue will sink to the bottom so allow 20-30 mm of LVN above it. This is the side that will be attached to the embedding block. The bottom will become the cutting surface so orient the tissue accordingly.

Pour a small amount of the A&E solution over the surface to cause the bubbles to rise and dissipate. Leave the dishes in a standard desiccator vented to the air for one to several weeks. Do not poke around in the LVN as it is drying. This can have a salting out effect creating a granular block that is impossible to cut. As a skin begins to form on the surface of the block, run a knife around its edge to allow air into the interior. When the block is firm enough to move, take it out of the container and place it on a flat surface in the desiccator turning it daily to ensure even drying. To cut 20 μ sections the block should be dried to the consistency of firm rubber. To cut 10 μ sections you should barely be able to dent the block with a fingernail. If the blocks dry out excessively pour 10 ml of A&E in the bottom of the desiccator. Slow even drying will produce blocks of uniform consistency and ease cutting.

MOUNTING AND CUTTING

To mount, trim the hardened tissue block with a razor blade leaving approximately 5 mm around the sides of the tissue and 15 mm on the side that will attach to the tissue block. Staple a double thickness of paper around a hard fiber embedding block forming a mold extending 30 mm above the block. Score the bottom and sides of the tissue block with a sharp pair of forceps and immerse in A&E for 20 seconds. Pour fresh thick LVN into the paper mold. Push in the tissue block, making sure that it is completely covered and at the correct orientation. Place the block in a half-filled jar of chloroform. The block will be hard enough to cut in three days but it can be stored for several months in the chloroform.

If the tissue is brittle run the mounted block through a series of chloroform : cedarwood oil solutions to give it tensile strength and ease cutting. Leave the block in 1 part cedarwood oil (immersion grade) to 3 parts chloroform for 24 hrs; then into a 1:1 solution for 24 hrs (Lillie and Fullmer, 1976) and finally into 100% cedarwood oil for 2 days. Blocks can be stored indefinitely in cedarwood oil. Blocks can also be stored indefinitely in 70% alcohol after the initial chloroform step, although this softens them somewhat.

Trim the block with a razor blade to several mm around the tissue and orient it on a sliding microtome. Leave enough LVN below the tissue to insure that it stays solidly affixed to the embedding block. It is easier to cut a head anterior to posterior. With soft tissue the direction is not important. The cutting stroke should be of an even moderate speed. A sharp clean knife is essential. Stropping is the best way to maintain a good edge. Keep the block wet with 70% alcohol by setting up a bottle of alcohol with a continuously dripping tube above the microtome. The knife should also be kept wet with alcohol. A thin film of honing oil applied to the knife surface before cutting will prevent rust formation. With a pair

of fine forceps pull the sections from the knife onto pieces of onionskin paper cut just larger than the section size. Place them in a small dish of 70% alcohol. When cutting is finished wrap the sections in cheesecloth, secure with a rubber band and store in 70% alcohol. We did not have success cutting cedarwood soaked blocks dry but used 70% alcohol on these as well.

STAINING

The LVN sections accept a variety of stains with excellent results. Adaptations for two staining sequences are included here. Hematoxylin and eosin is a good general stain. Picro-ponceau is a connective tissue stain that distinguishes muscle, bone and cartilage well. LVN dissolves in 100% alcohol so propanol must be substituted for the last dehydration step.

The sections can be mounted on slides for staining but it is more efficient to stain them in bulk and mount them afterwards using the illustrated staining trays (fig. 1). In transferring the sections keep them moist with 70% alcohol for they dry out very rapidly. Stack the trays in a dish with enough 70% alcohol to cover each sequential layering.

Hematoxylin and Eosin

1.	Distilled water	3 min
2.	Hematoxylin (Ehrlich's)	20 min
3.	Tap water	2 rinses
4.	Acid alcohol	quick dip
5.	Tap water	2 rinses
6.	Tap water with 6 drops $Li(CO_3)$	3 min
7.	Tap water	2 rinses
8.	Eosin	2-4 min
9.	70% ETOH	1 min
10.	95% ETOH	2 min
11.	Propanol	3 min
12.	Terpineol or Xylene	5 min or until ready to mount

Formulae for the hematoxylin and eosin can be found in Humason (1979). Acid alcohol contains 900 ml 70% ETOH and 10 ml HCL. $Li(CO_3)$ is a saturated aqueous solution.

Picro-ponceau

1.	Distilled water	3 min
2.	Hematoxylin (Weigert's)	15 min
3.	Running water	10 min
4.	Picro-ponceau	2-1/2 min
5.	Distilled water	2 rinses
6.	70% ETOH	1 min
7.	95% ETOH	2 min
8.	Propanol	3 min
9.	Terpineol or Xylene	5 min or until ready to mount

All formulae are in Humason (1979).

The stained sections are mounted in permount on glass slides, weighted and left to dry on warming trays. A few drops of a 10% methyl benzoate in xylene solution applied to the sections before coverslipping will flatten out wrinkled or bulky sections.

STAINING TRAYS

Trays for bulk staining of loose sections can be constructed from inexpensive, readily available material. The two trays illustrated can accommodate sections from 5 mm to 25x30 mm in size. Figure 1b was cut from a 'mini-cocktail' ice-cube tray available at hardware stores. Holes were drilled in the bottoms of each of the 15 mm straight-sided cubes to facilitate draining. In figure 1c six plastic bottoms from 'Tissue-Tek II Process/Embedding Cassettes' were melted together at the interfaces with a soldering iron to form a rigid tray. The trays are stacked and inserted in the tray holder (fig. 1a) constructed from two pieces of PVC plastic cut to fit the 9x12 cm metal staining dishes used in this lab. Wingnuts allow the whole ensemble, held together with four stainless steel screws, to be screwed down with sufficient force to keep sections from escaping.

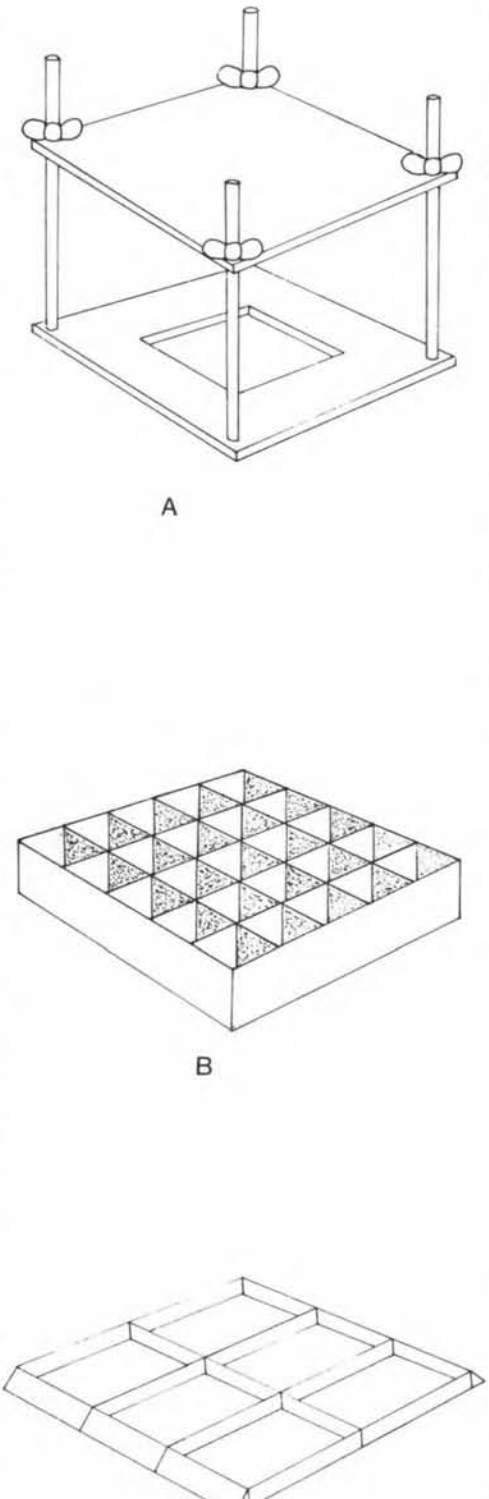

Figure 1. Construction of staining trays. A. Staining tray holder. B. Staining tray for smaller sections. C. Staining tray constructed for larger sections. (See text for further description.)

FREEZE-BRANDING: A LONG TERM MARKING TECHNIQUE ON LONG-TOED SALAMANDERS

We evaluated freeze-branding as a marking technique for salamanders. Freeze-branding has been successfully used on mammals, fish (Everest and Edmundson, 1967; Fujihara and Nakatani, 1967; Raleigh *et al.*, 1973), snakes (Lewke and Stroud, 1974), banana slugs, *Ariolimax columbianus* (Richter, 1973), and tailed frogs, *Ascaphus truei* (Daugherty, 1976). Recommended application times vary from 1.5 seconds with fish (Raleigh *et al.*, 1973) to 30 seconds with snakes (Lewke and Stroud, 1974). Freeze-branding selectively destroys chromatophores and alters pigmentation without disrupting other components of the integument (Lewke and Stroud, 1974). This technique produces a variety of marks quickly and economically, remains durable, and does not alter behavior; but there is a delay in the mark becoming visible (Lewke and Stroud, 1974). Our objective was to compare the clarity of brands among three application times on long-toed salamanders *(Ambystoma macrodactylum).*

METHODS

In April 1978, 30 long-toed salamanders were collected and held in the laboratory. Each was toe clipped for identification (Twitty, 1966) and branded on the dorsal surface. We used letter brands 5 mm in height made with copper rods and silver tips (Raleigh *et al.*, 1973). Each brand was cooled 5 minutes in a thermos filled with liquid nitrogen and reimmersed for at least 30 seconds prior to reuse. We branded 10 salamanders for 0.75 seconds, 10 for 2 seconds, and 10 for 4 seconds. The condition of each salamander and brand legibility were recorded daily for 3 days after branding and at intervals of 1, 3, and 6 months. The clarity of each brand was recorded as: easily identified, barely identified, and unidentifiable.

RESULTS AND DISCUSSION

The skin turned white for 2-3 seconds after contact with the brand before returning to natural color. An hour later, the brand appeared as a darkening of the skin. Clarity increased with time, and the brands became legible as dark imprints after 1 to 3 days. Two animals branded for 4 seconds temporarily lost mobility in the limbs, but no adverse effects were observed after 24 hours, and no salamanders developed infections. Mortality occurred when the storage facility (refrigerator) malfunctioned and four of the salamanders froze. We did not attribute any mortality to the branding.

The 0.75-second application produced the cleanest, most readable marks (Table 1). Maximum clarity of brands was obtained after 3 months, although the same trends were evident at the 1 and 6 month recordings. Brand quality deteriorated as application time increased. Longer branding times probably froze adjacent tissues and blurred the mark.

Table 1. Clarity of brands (%) at different application times on long-toed salamanders after 3 months.

Application	Brand clarity[1]			n
time (seconds)	+	0	-	
0.75	50	50	0	8
2.0	30	30	40	10
4.0	12.5	37.5	50	8

[1] Clarity categories are: (+) easily identified, (0) barely identified, (-) unidentifiable.

A BACK MARKER FOR INDIVIDUAL IDENTIFICATION OF SMALL LIZARDS

Behavior studies often require identification of specific individuals. We were interested in identifying individual *Emoia physicae* (Duméril and Bibron), 1839, a small New Guinea skink, from a distance but found general methods used for marking other lizards (Ferner, 1979) unsatisfactory for this species. We report here on a technique that allowed us to identify individuals from a distance of at least 6 m.

Adult males of *E. physicae* that we marked ranged from 153 to 210 mm, and adult females, from 140 to 189 mm in total length; snout-vent lengths were 66 to 75 mm and 63 to 73 mm, respectively. This species has small (± 1.0 x 1.5 mm, exposed surface) cycloid-like scales that make retention of some kinds of marks difficult.

We marked lizards with a pressure sensitive rip-stop nylon tape that is manufactured for mending such things as nylon tents and jackets and is distributed by Coghlan's Ltd., Winnipeg, Canada. Tape was applied to the back after washing the skin with 95% alcohol. We detected no adverse effects of this tape on individuals.

The size of our markers was about 5 x 10 mm, rounded at the corners to help prevent peeling. We coded the tapes with 2 colors of artists' acrylic paint and this lasted very well if allowed to dry thoroughly, about 30 minutes, before the lizard was released into a pen.

Over a 3-month period, we held 66 lizards marked with nylon tape in outside arenas (5 x 5 m) at the Wau Ecology Institute in Papua New Guinea. Four separate behavioral trials were run, lasting 11, 14, 13, and 12 days, respectively. Different individuals were used in each trial, with 50% of the lizards in the pens for each trial period and the other 50% for 1/2 of each trial period. One lizard lost its mark, 2 died with marks intact, and 1 disappeared. Fifteen lizards shed their skins during the trials and 11 markers attached to shed skin were recovered from the pens; 4 were not found. All lizards had been toe-clipped and were recaptured and re-marked within one day if they shed their skin during a trial. None lost a second mark.

Marked lizards were observed from a 2-1/2 m tower from about 1 m outside the edge of an arena. Non-moving individuals were readily identified with the naked eye anywhere in the pens. Moving individuals were easily identified with binoculars.

This technique allowed us to identify individuals from a distance for at least 2 weeks, or until shedding of the skin. We do not know how often *E. physicae* molts, but we suspect that it is fairly frequent because about 25% of our animals shed their skins during the 11 - 14 day trials. We suspect that the life span of the marks we used is considerably longer than the 2 week minimum that our data indicate, for all were in good condition at the termination of each trial.

Other marks that we had attempted to use on this species included artists' acrylic paint, either alone or mixed with 5-minute epoxy glue, both applied directly on the skin, and plasticized or adhesive tape pressed onto the neck or back (after washing the skin with alcohol). Paint or the paint/glue mixture normally peeled off within 2 - 3 days and the two kinds of tape within 5 - 10 days. We also attempted to mark lizards by placing small harnesses made of thread, each carrying an adhesive tape back-tab, just behind the front legs or just in front of the hind legs of individuals. *E. physicae* has small limber legs and was able to slip out of the harness unless we made them so tight that they restricted growth. None of these techniques was considered successful.

This study was done at Wau Ecology Institute, Wau, Papua New Guinea. Funding was provided by the Natural Sciences and Engineering Research Council of Canada. Personnel of Wau Ecology Institute provided logistic support for constructing arenas and our observation tower. R. A. Lewis, Department of Zoology, University of Alberta, provided critical comments on an early draft of the manuscript. We are grateful for all support received.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

CAUDATA

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). USA: DELAWARE: New Castle Co: On Route 463, about 60 meters W junction with Route 36 (and 3.7 km SSW of Townsend), 1 August 1973, Rudolf G. Arndt, verified by Rudolf G. Arndt. Carnegie Museum of Natural History (CM 92895, 92896). Two highly active recently transformed specimens (10.5 cm and 10.7 cm total length) taken on a blacktop road between 2200 and 2300 hours during a moderate rain after a two- to three-week period of drought; air temperature approximately 28° C. The capture area is mature deciduous forest with several wooded ponds. First record for the county. Extends the range some 27 km NW of the nearest known Delaware locality (near Dover, Kent County, R. Conant, pers. comm., 1983). The capture area is to date (1983) apparently undisturbed, which strongly suggests that this population of the eastern tiger salamander is extant.

PLETHODON LARSELLI (Larch Mountain Salamander). USA: WASHINGTON: Klickitat Co: 7.8 km W of Lyle. 18 February 1983. (A00294). Skamania Co: 9.5 km W of Archer Mt. 16 February 1983. (A00276-278); 9.8 km NE of Stabler. 8 March 1983. (A00350); 8.3 km n of Willard. 2 May 1983. (A00276-278). R. E. Herrington. Verified by J. H. Larsen, Jr. All specimens deposited in the collection of the Department of Zoology, Washington State University. First record for Klickitat County. Skamania County specimens indicate an inland penetration of 18 km from the Columbia River. New localities increase the potential range of *P. larselli* in Washington from approximately 80 km^2 (Nussbaum, Brodie and Storm, 1983, Amphibians and Reptiles of the Pacific Northwest) to 1100 km^2. Twelve additional populations have been identified within the area of the new localities. Study supported by the Washington Department of Game.

SIREN INTERMEDIA NETTINGI (Western Lesser Siren). USA: ARKANSAS: Yell Co: 0.5 km SW Petit Jean Wildlife Management Area headquarters, in Pond Creek. 11 March 1983. Collected by John Gallagher. Verified by G. D. Turnipseed. Arkansas Tech University Herpetological Collection (GDT 321), two specimens. The specimens were found in the debris from a dynamited beaver dam. The nearest previously reported specimens are from the Arkansas Tech University campus, Russellville, Arkansas, approximately 31 km to the NW (Turnipseed, G. D. 1980. Geographic distribution: *Siren intermedia nettingi*. SSAR Herp. Review 11(1):32).

ANURA

RANA CLAMITANS MELANOTA (Green Frog). USA: ARKANSAS: Washington Co: 24.1 km W of Fayetteville in entrance zone of Savoy Cave near Illinois River-Clear Creek confluence. 14 November 1982. S. E. Trauth and C. T. McAllister. Verified by R. S. Caldwell. Arkansas State Univ., Herpetological Museum (ASUHM #4044). A new county record (Dowling, H. G. 1957. Occ. Pap. U. Ark. Mus. 3:1-51) and the second reported individual from an Arkansas cave (see McDaniel, V. R. and J. E. Gardner. 1977. Proc. Ark. Acad. Sci. 31:68-71). Black (1973. Proc. Okla. Acad. Sci. 53:33-37) reported juvenile green frogs from the twilight zone of an Oklahoma cave. Our specimen, a male (head length = 22.0 mm, tibia length = 34.6 mm) was a cave accidental utilizing the site for shelter (outside air temp.= 5.0° C; cave water temp.= 11.5° C). Ecological associates included *R. catesbeiana, Eurycea longicauda melanopleura, E. lucifuga, E. multiplicata griseogaster* and *Plethodon glutinosus.*

TESTUDINES

CHRYSEMYS SCRIPTA ELEGANS (Red-eared Turtle). USA: TEXAS: Rockwall County: Rowlett. Collected on SR 66 next to Lake Ray Hubbard. 31 October 1982, Steven Myers. Verified by P. A. Meylan. Florida State Museum, University of Florida (UF 53447). This specimen represents a new county record (Raun and Gehlbach, 1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2).

Submitted by **STEVEN MYERS,** Department of Biological Sciences, University of Central Florida, Orlando, Florida 32816. ●

SAURIA

ANNIELLA NIGRA ARGENTEA (Silvery Legless Lizard). MEXICO: BAJA CALIFORNIA: Trib. Rio San Carlos, 20 km SE of the turnoff to Ojos Negros, along Mexican Highway 3 (=BCN16). 29 April 1979. This site is about 60 km ESE Ensenada. Collected and identified by the author. National Museum of Natural History (USNM 225333-334). There are few inland records of *Anniella* in Baja California, and prior accounts do not seem to define accurately the range of the species in Baja California. Van Denburgh (1922. The Reptiles of North America. Calif. Acad. Sciences), Klauber (1932. Copeia:4-6), and Shaw (1949. Herpetologica 5:27-28) report specimens from San Jose (Meling Ranch) at about latitude 31° N. L. E. Hunt (pers. comm.) provided records from near La Rumorosa (San Diego Natural History Museum 57373 and California Academy of Sciences 123702-705), which is near the U.S.-Mexico border at about lat. 32° 30'N. The Ojos Negros locality along Highway 3 is at about 31° 52'N, and fills in a gap of about 175 km between the other two inland records. Van Denburgh and Klauber both reported *Anniella* from San Salado Canyon, which is probably also known as Arroyo Salado, about 19 km S of San Vicente along Highway 1 (Wheelock, W. and H. E. Gulick. 1975. Baja California Guidebook. A. H. Clark Co.). This is a Pacific coastal site and is not to be confused with Laguna Salada near Mexicali. Bezy et al. (1977 Syst. Zool. 26:57-71) indicate that the range of *Anniella* is only in northwestern Baja California. Stebbins (1966. Field Guide to Western Reptiles

and Amphibians. Houghton Mifflin Co.) shows the range of *Anniella* extending to the Gulf of California in northern Baja California. R. C. Stebbins (pers. comm.) based this record on Gorman (1957. Copeia:148-150), who shows a locality near San Felipe on the Gulf of California. J. Gorman (pers. comm.) kindly reported to me that the locality probably mistaken by him to be near San Felipe was recorded as a specimen from "SDNHM 16284 BC Sta Maria n 4 mi. (Arroyo Paballon)." Santa Maria (along Arroyo or Rio Pabellon) is near San Quintin on the Pacific coast of the Baja California peninsula. Seemingly, Gorman earlier confused this locality with Junta Santa Maria, which is about 18 km S of San Felipe and at the same latitude as Santa Maria (Rio Pabellon) on the west coast. Also, the specimen number is probably SDNHM 41862 (L. E. Hunt, pers. comm.). To my knowledge, there are no records of *Anniella* east of the Sierra de Juarez and Sierra San Pedro Martir of Baja California. This clarification is shown in the range map of Hunt (1983. Copeia:79-89).

EUMECES ANTHRACINUS PLUVIALIS (Southern Coal Skink). USA: KENTUCKY: Calloway Co: 0.9 km north of Rte 121 on Rte 280. 22 June 1983. J. Moriarty, M. Evans, T. Sheehan, and W. Burger. Verified by J. R. MacGregor. Kentucky Nature Preserves Commission (KNPC H1076). This is the first record of this subspecies for the state. This extends the range east of the Mississippi River north by 175 km. (Mount, 1975. Reptiles and Amphibians of Alabama. Auburn).

Submitted by **JOHN MORIARTY,** Kentucky Nature Conservancy, Box 4207, Lexington, Kentucky 40544 and **MARC EVANS,** Kentucky Nature Preserves Commission, 407 Broadway, Frankfort, Kentucky. 40601. ●

EUMECES EGREGIUS ONOCREPIS (Peninsula Mole Skink). USA: FLORIDA: Indian River County: 4 miles south of Vero Beach, near jct. of Old Dixie Hwy. and Kelly Rd. 19 November 1977, Steven Myers. Verified by P. A. Meylan. Florida State Museum, University of Florida (UF 45794). Collected under boards in Rosemary Scrub. First published record of *Egregius* from Indian River County. Fills gap in distributional hiatus between Brevard and St. Lucie Counties (Mount, 1965, Variation and Systematics of the Scincoid lizard, *Eumeces egregius* (Baird), Bull. Fla. Sta. Mus. 9(5):184-213.

Submitted by **STEVEN MYERS,** Department of Biological Sciences, University of Central Florida, Orlando, Florida 32816. ●

HEMIDACTYLUS GARNOTI (Indo-Pacific Gecko). USA: FLORIDA: Orange Co: ca. 5.0 km NE Union Park (T22S, R31E, Sec. 9). 27, 29 March 1983. R. E. Smith, M. R. Bolt, J. M. Bloodwell. Verified by Peter Meylan. Florida State Museum (UF/FSM 53909-53910). Snout-vent length 52.0 mm and 53.1 mm, respectively. Geckos were initially observed on walls of newly constructed and landscaped apartment building in summer and fall 1982. *Hemidactylus turcicus* is absent from this locality. New county record. Northernmost record for this species. First recorded non-coastal sighting since introduction into Florida prior to 1964 (King and Krakauer, 1966, Quart. J. Fla. Acad. Sci. 29(2):144-154). Although Myers published first Brevard Co. record (Myers, S. 1979. SSAR Herp. Review 10(3):102-103), Cooper and Thompson's collections from Merritt Island (UF/FSM 44142, 44148; unpubl.) represent northernmost east coast locality. Union Park record lies ca. 61.1 km W-NW of Merritt Island locality and ca. 249.5 km N-NE of northernmost west coast record from Sanibel Island (McCoy, C. 1972. SSAR Herp. Review 4(1):23).

Submitted by **RICHARD E. SMITH,** Department of Biological Sciences, University of Central Florida, P.O. Box 25000, Orlando, Florida 32816. ●

LEIOLOPISMA LATERALE (Ground Skink). USA: TEXAS: Rockwall County: Rockwall, Lake Ray Hubbard. 9 October 1982, Steven Myers. Verified by P. A. Meylan. Florida State Museum, University of Florida (UF 53454). Collected under a trash pile on the shore of the Lake. First published record of *Leiolopisma* from Rockwall County (Raun and Gehlbach, 1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2). This together with the Rains County record helps to fill the last few distributional gaps in East Texas (Raun and Gehlbach, 1972).

Submitted by **STEVEN MYERS,** Department of Biological Sciences, University of Central Florida, Orlando, Florida 32816. ●

LEIOLOPISMA LATERALE (Ground Skink). USA: TEXAS: Rains County: East Towakoni, Lake Towakoni. 6 November 1982, Steven Myers and Rick Nappi. Verified by P. A. Meylan. Florida State Museum, University of Florida (UF 53452-53453). These specimens were found under a trash pile near the shore of the lake. This represents the first published record of *Leiolopisma* from Rains County (Raun and Gehlbach, 1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2).

Submitted by **STEVEN MYERS,** Department of Biological Sciences, University of Central Florida, Orlando, Florida 32816. ●

SERPENTES

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). USA: INDIANA: Dubois Co: Buffalo Bottoms, 2 km northeast of Jasper. Collected 4 May 1983 by John Krempp and Phil Schuetter. Verified by S. A. Minton and A. B. Wilson who observed two additional cottonmouths at this locality on 8 May 1983. Voucher specimen in Minton Collection (No. 1876). First record of the species for Indiana. Extends the known range 73 km E of previous record for Mount Carmel, Illinois (Cope, 1877. Am. Phil. Soc. Proc. 17 (100):63-68) and 101 km NE of previous record for Union County, Kentucky (Lodato and Burnley, 1975, Kentucky Herpetologist 5:4).

Submitted by **ANTHONY B. WILSON,** Indiana Department of Natural Resources (Enforcement Division), Indianapolis, Indiana 46204 and **SHERMAN A. MINTON,** Indiana University School of Medicine, Indianapolis, Indiana 46223. ●

CONTIA TENUIS (Sharptail Snake). USA: WASHINGTON: Skamania Co: 6.7 km NE of Carson. 2 May 1983. R. E. Herrington. Verified by J. H. Larsen, Jr. Department of Zoology, Washington State University. (A00551). Specimen is an adult female collected at 500 m elevation from an exposed talus slope. Locality is 4 km W of the Cascade Crest and extends the range 35 km W of the only other record for southern Washington (Stebbins, 1966, Field Guide to Western Reptiles and Amphibians). Study supported by the Washington Department of Game.

Submitted by **ROBERT E. HERRINGTON** and **JOHN H. LARSEN, JR.,** Department of Zoology, Washington State University, Pullman, Washington 99164. ●

DRYMARCHON CORAIS COUPERI (Eastern Indigo Snake). USA: FLORIDA: Indian River County: Wabasso Beach, DOR at the intersection of Jungle Trail and SR ALA. 8 December 1982, Steven Myers and Gary Tinsley. Verified by P. A. Meylan. Florida State Museum, University of Florida (UF 53465). This male specimen represents the first catalogued voucher specimen from Indian River County. An uncatalogued specimen collected by Herbert W. Kale II 31 October 1966 on the property of the Florida Medical Entomology Laboratory, South of Vero Beach is at that institution. Although the Eastern Indigo Snake is included in the Florida List of Rare and Endangered Species, it appears to be abundant in Indian River County particularly in citrus groves and coastal hammocks. I have also observed *Drymarchon* abundantly in these situations in St. Lucie County. It has been recorded from the surrounding counties of Brevard, Osceola, and Okeechobee (Ashton and Ashton, 1981, Handbook of Reptiles and Amphibians of Florida, Part I, The Snakes, Windward Publishing, Inc.).

Submitted by **STEVEN MYERS,** Department of Biological Sciences, University of Central Florida, Orlando, Florida 32816. ●

NERODIA HARTERI HARTERI (Brazos Water Snake). USA: TEXAS: Haskell Co: just below Lake Stamford Dam, 19 km ESE of Haskell. 3 August 1965, 4 April 1967, and 8 August 1968. Donald D. Smith. Verified by Donald D. Smith. Bobby Witcher Memorial Collection, Avila

College, Kansas City, Missouri (BWMC 2028-2029), and University of Kansas, Museum of Natural History, Lawrence, Kansas (KU 193260-193266). These specimens represent a county record, and extend the range of this snake approximately 18 km to the west of the Throckmorton County record of Tinkle and Knopf (1964, Herpetologica, 20(1):42-47).

Submitted by **DONALD D. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th Street and Rainbow Boulevard, Kansas City, Kansas 66103. ●

THAMNOPHIS RADIX HAYDENI (Western Plains Garter Snake). USA: MISSOURI: Carroll Co: 10.4 km south of Carrollton on US Highway 24. 1 May 1983. D. D. Smith and R. Powell. Verified by R. Powell and D. D. Smith. Avila College, Bobby Witcher Memorial Collection (BWMC 1987). The adult male is the first record from Carroll County, approximately 60 km SSE and 50 km SSW of the nearest reported localities in Livingston and Chariton Counties respectively, and extends the known distribution in central Missouri to the Missouri River flood plain (Anderson, 1965. The Reptiles of Missouri. Univ. Mo. Press, Columbia. p. 162). The capture site was due south of the proposed zone of intergradation between *T. r. radix* and *T. r. haydeni*, but this specimen is attributable to the latter with 21 cervical dorsal scale rows and 162 ventrals. We suggest that the southern limit of distribution of this snake in Missouri parallels the Missouri River, with dispersal being facilitated by occasional flooding in a manner proposed for Great Plains anurans by Metter et al. (1970. Copeia 1970(4): 780-781).

Submitted by **ROBERT POWELL,** Department of Natural Sciences, Avila College, 11901 Wornall Road, Kansas City, Missouri 64145, and **DONALD D. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th Street and Rainbow Boulevard, Kansas City, Kansas 66103. ●

NEW DISTRIBUTIONAL RECORDS OF TEXAS AMPHIBIANS AND REPTILES

The records reported herein add to the distributional data for some species of amphibians and reptiles in Texas. These records supplement those of Raun and Gehlbach (1972), Lewis (1974), Hambrick (1975, 1976), Merkord (1975), Cys (1976), Mather and Dixon (1976), and Karges (1978, 1979, 1981). Unless discussed as a range extension or range-margin extension, specimens represent new county records. Voucher specimens from counties hitherto represented by literature records only, are indicated by asterisk following the county name. All specimens are deposited in the Stephen F. Austin State University Collections. All identifications and verifications were made by the authors. Nomenclature follows Collins, et al. (1978).

CAUDATA

Ambystoma maculatum (Spotted Salamander): CASS Co. * SFA-5028. 8 km S Atlanta. 13 April 1973. R. Jackson. SAN AUGUSTINE Co. SFA-4853. 8.4 km NNW Broaddus. 4 March 1981. V. Rakowitz. This record is a range-margin extension westward from adjacent Sabine Co.

Ambystoma opacum (Marbled Salamander): NEWTON Co. SFA-160. 16.1 km E Burkeville. 30 November 1957. E. Toole. RUSK Co. * SFA-2087. Cannon's Ranch. 13 October 1962. C. Burrows.

Ambystoma talpoideum (Mole Salamander): RED RIVER Co. SFA-4718. 24.1 km N Clarksville. 26 April 1975. F. Rainwater. This specimen represents a range extension 223 km northward from previously recorded Texas populations. This is a partial link between the east Texas and southeastern Oklahoma populations. SAN AUGUSTINE Co. SFA-4854, 4855, 4856, 4857, 4858. 8.4 km NNW Broaddus. 13 April 1980. V. Rakowitz. These specimens bridge the gap between Jasper Co. to the south and Nacogdoches Co. to the north.

Ambystoma texanum (Smallmouth Salamander): ANGELINA Co. SFA-4209. Lufkin. 19 March 1969. G. Jacobs. KAUFMAN Co. SFA-3669. 8 km N Kaufman. 1 March 1969. K. Skidmore. SFA-3688, 3689. 9.6 km N Kaufman. 4 April 1969. K. Skidmore. SFA-3712. 8 km E Seagoville on FM rd. 5. 22 March 1969. K. Weatherford. NEWTON Co. SFA-183. 16.1 km E Burkville. 8 December 1957. E. Toole. SABINE Co. SFA-3969. 24.1 km N Hemphill. 8 March 1969. B. McDowell.

Ambystoma tigrinum mavortium (Barred Tiger Salamander): ARMSTRONG Co. * SFA-3194. 11.3 km W of Claude on FM rd. 1151. 22 August 1965. C. Mather. *Ambystoma tigrinum* (Eastern Tiger Salamander): NACOGDOCHES Co. * SFA-3773. 3.2 km N Nacogdoches. 27 January 1969. J. Leach.

Amphiuma tridactylum (Three-toed Amphiuma): ANGELINA Co. SFA-2417. 1.6 km S of Angelina River bridge on TX. 21. 15 May 1966. A. Foley. This record is a range-margin extension northwestward from Tyler Co. CHEROKEE Co. SFA-2561. 11.3 km S of Alto on TX. 21. 4 July 1966. W. Holder. This specimen is a range-margin extension southward from Smith Co. NACOGDOCHES Co. * SFA-2585 through 2595. On S.F.A. campus in Nacogdoches. 23 February 1966. J. Lock. SFA-3008. Banita Creek in Nacogdoches. 18 March 1967. J. Shaw. NEWTON Co. SFA-1884. 1.6 km S Old Columbia. 27 April 1961. J. Hurst.

Desmognathus auriculatus (Southern Dusky Salamander): ANDERSON Co. SFA-2363. 14.5 km E Palestine. 8 October 1964. S. Hillis. CHEROKEE Co. SFA-223. 2.4 km N Galatin. 18 January 1958. J. Collins. The specimens from Cherokee and Anderson Counties represent successive range-margin extensions to the west of Nacogdoches Co.; a westward range extension of 50 km.

Necturus beyeri (Gulf Coast Waterdog): CHEROKEE Co. SFA-2562. 10.5 km E of Jacksonville. 18 June 1966. K. Griffin. This specimen represents a range-margin extension to the west from adjacent Nacogdoches and Rusk Counties.

Notophthalmus viridescens louisianensis (Central Newt): NACOGDOCHES Co. SFA-383, 746, 909, 1295, 1831, 2128, 3002, 3849, 4057, 4750. The ten specimens listed above are from various locations within the county and were collected from 1957 through 1978. RUSK Co. SFA-3332. Intersection of U.S. 84 and FM rd. 839. 17 November 1967. C. Mather.

Siren intermedia nettingi (Western Lesser Siren): NACOGDOCHES Co. * SFA-2418. Nacogdoches. 10 March 1966. P. Thornburgh. SFA-2419. Nacogdoches. 24 June 1966. M. Land. SFA-2596, 2597, 2598. S.F.A. Campus, Nacogdoches. 23 February 1966. J. Lock. SFA-3367. 16.1 km SW Nacogdoches. 4 April 1968. C. Meitzen. SFA-3439. 4.8 km W Nacogdoches on TX. 7. 25 March 1969. J. Malloy. SFA-4367. Nacogdoches. 24 February 1971. R. Dorman. SFA-4368. Nacogdoches. 26 February 1971, D. Herbert. PANOLA Co. SFA-2677. 3.2 km SW Carthage. 16 October 1964. W. Gullette.

SALIENTIA

Acris crepitans blanchardi (Blanchard's Cricket Frog): FORT BEND Co. * SFA-2816. 6.4 km S Rosenberg. 28 March 1967. C. Meitzen. NUECES Co. SFA-1416. 16.1 km S Port Aransas. 23 July 1960. R. Packard. ROCKWALL Co. SFA-3700. S shore Lake Ray Hubbard. 1 March 1969. K. Weatherford. VAN ZANDT Co. SFA-2961. 11.2 km N Canton. 12 March 1967. M. Robinson.

Acris crepitans crepitans (Northern Cricket Frog): GREGG Co. SFA-1647. 11.3 km E Kilgore. 22 October 1960. J. Kincaid.

Bufo speciosus (Texas Toad): FAYETTE Co. SFA-3911. Schulenburg. 12 April 1969. T. Frizzell. GARZA Co. * SFA-4602. 11.3 km NE Post. 17 June 1973. S. Restivo.

Bufo valliceps valliceps (Gulf Coast Toad): BREWSTER Co. SFA-4445. On TX. 118, N of Study Butte. 24 July 1971. F. Rainwater. This record is a range-margin extension westward from adjacent Terrell Co. COMANCHE Co. SFA-3591. 6.4 km E DeLeon. 18 April 1969. B. Garrett. This specimen represents a range extension westward of 47 km from the nearest county record, Bosque Co. NACOGDOCHES Co. * SFA-752. Nacogdoches. 27 September 1959. R. Packard. SFA-1177. 0.4 km E Nacogdoches. 18 July 1960. J. Bowers. SFA-3709. Nacogdoches. 10 February 1969. K. Weatherford. SABINE Co. SFA-3975. 24.1 km N Hemphill. 29 March 1969. B. McDowell. This record fills the distribution gap between Shelby Co. to the north and Jasper Co. to the south.

Bufo woodhousei fowleri (Fowler's Toad). GALVESTON Co. SFA-2865. West Lagoon, Galveston. 19 April 1967. R. Dutcher. SFA-3009. Lagoon area, Galveston. 15 April 1967. J. Shaw. SAN AUGUSTINE Co. SFA-1183. 4.8 km NW San Augustine. 8 June 1960. D. Alford. SFA-1190. 4.8 km NW San Augustine. 15 June 1960. D. Alford. SFA-4859. 1.6 km NNE Broaddus. 8 March 1981. V. Rakowitz. VAN ZANDT Co. * SFA-2963. 11.3 km N Canton. 18 March 1967. M. Robinson.

Bufo woodhousei woodhousei (Woodhouse's Toad): WARD Co. SFA-4390. 8 km

NE Monahans. 3 April 1971. S. Restivo and J. Schultz. WINKLER Co. SFA-4392. 14.5 km NE Kermit. 23 June 1966. C. Kauffman. SFA-4393. 8 km NE Kermit. 2 April 1971. S. Restivo and J. Schultz. SFA-4580. 16.1 km NE Kermit. 20 May 1972. S. Restivo. The Ward and Winkler county specimens confirm their presence in an area previously mapped by Conant (1975) as a disjunct population.

Gastrophryne carolinensis (Eastern Narrowmouth Toad): ANGELINA Co. SFA-3715. 12.9 km NW Lufkin. 19 March 1969. K. Weatherford. SFA-4062. Clawson. 19 March 1969. J. Vincent. SAN AUGUSTINE Co. SFA-4860. 8.4 km NNW Broaddus. 20 April 1981. V. Rakowitz.

Gastrophryne olivacea (Great Plains Narrowmouth Toad): LAMPASSAS Co. SFA-4375. 6.4 km N Bend. 10 April 1970. D. Wood.

Hyla cinerea (Green Treefrog): ANGELINA Co. * SFA-3466. Hank's Creek marina, Sam Rayburn reservoir, 3 May 1969. B. Bates. PANOLA Co. SFA-1336. 6.4 km W, 3.2 km S Carthage. 29 June 1960. P. Osborne. SFA-2670. Carthage. 26 October 1964. W. Gullette. SAN AUGUSTINE Co. SFA-4884. 5.6 km N Broaddus on Forest Service Rd 300-1. 3 May 1982. R. Fleet.

Hyla crucifer crucifer (Northern Spring Peeper): JEFFERSON Co. SFA-3049. 4.8 km W Beaumont. 27 March 1967. B. Bilbo. SAN AUGUSTINE Co. SFA-3981. San Augustine. 18 April 1969. B. McDowell.

Hyla squirella (Squirrel Treefrog) NACOGDOCHES Co. SFA-3738. 24.1 km NE Nacogdoches. 1 March 1969. R. Harrell. This specimen represents a range extension 88 km northward from the nearest county record, Tyler County.

Pseudacris streckeri streckeri (Strecker's Chorus Frog): LEON Co. * SFA-4070. Buffalo. 26 April 1969. J. Vincent. NACOGDOCHES Co. * SFA-31. 9.6 km SW Nacogdoches. 18 October 1957. B. Hyndman. PANOLA Co. SFA-2655. Junction of FM rds. 10, 999 and 1970 at Gary. 26 November 1964. L. McWilliams. SFA-2656. 19.3 km SW Carthage. 24 November 1964. W. Gullette. These two specimens represent a range-margin extension eastward from adjacent Rusk Co. ROBERTSON Co. SFA-587. 6.4 km E Benchly. 7 December 1951. P. Parmalee. SHELBY Co. SFA-3716. 16.1 km NE Hurstown, Sabine National Forest. 26 April 1969. K. Weatherford. This record is a range-margin extension eastward from adjacent Nacogdoches County. UPSHUR Co. SFA-4781. 11.3 km W Gilmer. 18 March 1978. B. Reed.

Pseudacris triseriata feriarum (Upland Chorus Frog): POLK Co. * SFA-2654. 1.6 km S Corrigan. 10 October 1964. R. Chisolm. SABINE Co. SFA-3985, 3986. 24.1 km N Hemphill. 26 April 1969. B. McDowell.

Rana areolata areolata (Southern Crawfish Frog): NAVARRO Co. SFA-4544. 16.1 km E Corsicana on U.S. 287. 28 March 1972. G. Connor. This specimen is a range-margin extension west from Anderson County.

Rana blairi (Plains Leopard Frog): DONLEY Co. * SFA-3191. Salt Fork of the Red R., N of Ashtola. 25 August 1965. C. Mather. POTTER Co. * SFA-3170. Canadian R., 24.1 km N Amarillo on U.S. 287. 17 July 1965. C. Mather.

Rana catesbeiana (Bullfrog): ANGELINA Co. SFA-322. 6.4 km W Lufkin. 15 April 1958. J. Collins. SFA-2850. Lufkin. 29 April 1967. R. Diamond. SFA-4231. 4232. Lufkin. 12 April 1969. G. Jacobs. FORT BEND Co. SFA-2813, Brazos River bottom. 26 March 1967. C. Meitzen. GREGG Co. * SFA-1646. 11.3 km E Kilgore. 22 October 1960. J. Kinkaid. NACOGDOCHES Co. * SFA-1485, 1486, 1910, 1914, 1923, 1956, 1961, 2514, 2515, 2665, 2678, 4060. These twelve specimens are from various locations within the county and were collected from 1960 through 1969. PANOLA Co. SFA-2416. 16.1 km E Carthage. 20 June 1966. H. LaGrone. SFA-2663. 8 km S Carthage on U.S. 59. 8 January 1965. R. Anderson. SFA-4126. 6.4 km N Tenaha. 3 April 1969. R. Fetterolf.

Rana clamitans clamitans (Bronze Frog): ANGELINA Co. * SFA-2511. 3.2 km W Lufkin State School. 3 July 1966. A. Foley. SFA-2862. Lufkin. 4 May 1967. R. Dutcher. SFA-3457. Hank's Creek marina, Sam Rayburn Reservoir. 3 May 1969. B. Bates.

Rana sphenocephala (Southern Leopard Frog): ANGELINA Co. SFA-3464, 3465. Hank's Creek marina, Sam Rayburn Reservoir. 3 May 1969. B. Bates. SFA-4201, 4202. Lufkin. 17 March 1969. G. Jacobs. SFA-4203. Lufkin. 18 March 1969. G. Jacobs. SFA-4204, 4205. Lufkin. 19 March 1969. G. Jacobs. PANOLA Co. SFA-2498. 8 km W Carthage on TX. 315. 18 June 1966. W. Gullette. SFA-2686. 4.8 km S Carthage on Hill's Lake Rd. 22 December 1964. R. Anderson. SFA-2687. 4 km SW Carthage on Dixie Lake Rd. 18 October 1964. W. Gullette. SMITH Co. SFA-2689. Tyler. 25 October 1964. R. Moss.

Scaphiopus bombifrons (Plains Spadefoot): WILLACY Co. SFA-4377. 9.6 km W Raymondville on TX. 186. 4 April 1971. J. Jacob. WINKLER Co. SFA-5002. 1.6 km N junction TX. 115 and FM rd. 1218. 3 June 1972. J. Schultz. This specimen provides a link in the distribution gap between the Trans-Pecos and Texas Panhandle populations.

Scaphiopus couchi (Couch's Spadefoot): MIDLAND Co. * SFA-3588. Midland. 4 April 1969. B. Garrett.

Scaphiopus hammondi (Western Spadefoot): LUBBOCK Co. * SFA-4605. through 4611. 8 km SE Lubbock. 17 June 1973. S. Restivo.

Scaphiopus holbrooki hurteri (Hurter's Spadefoot): CHEROKEE Co. SFA-3699. 1.6 km N Jacksonville. 5 April 1969. K. Skidmore. SFA-3786, 3787, 3788, 3789. Jacksonville. 7 April 1969. J. Leach. GREGG Co. SFA-1651. Kilgore. 26 November 1960. J. Kincaid. HOUSTON Co. SFA-293. 4.8 km E Ratcliff. 7 March 1958. J. Collins. PANOLA Co. SFA-747. 3.2 km E Gary. 21 November 1959. R. Packard. SFA-2658. Junction of FM rds. 10, 999 and 1970 at Gary. 26 November 1964. L. McWilliams. POLK Co. SFA-2936. 1.6 km S Neches River. 7 April 1967. J. Birch. SAN AUGUSTINE Co. SFA-4861. 7.6 km NNW Broaddus. 20 April 1981. V. Rakowitz.

TESTUDINES

Chelydra serpentina serpentina (Common Snapping Turtle): HENDERSON Co. * SFA-4045. Malakoff. 12 April 1969. M. Lewis. NACOGDOCHES Co. SFA-1185, 1477, 1478, 2618, 2958, 3594, 3618, 4135, 4589. These nine specimens were collected from various localities within the county from 1960 through 1972. RUSK Co. SFA-2904. 3.2 km E Overton. 3 April 1967. J. Bynum. SHELBY Co. SFA-1308. 3.2 km S Center. 14 June 1960. J. Martin. SMITH Co. * SFA-2736. Tyler. 29 March 1967. M. Vredenburg.

Chrysemys concinna texana (Texas River Cooter): PALO PINTO Co. SFA-4799. Brazos River 8 km downstream from TX. 16 bridge. 9 April 1977. T. Truax. SAN SABA Co. SFA-4786. 16.1 km ESE San Saba. 23 April 1978. R. Marr.

Chrysemys scripta elegans (Red-eared Slider): ANGELINA Co. SFA-4210. Lufkin. 20 March 1969. G. Jacobs. SFA-4226. Lufkin. 31 March 1969. G. Jacobs. JASPER Co. SFA-4694. Jasper State Fish Hatchery. 18 April 1975. M. Hamilton. SHELBY Co. SFA-4131. 0.4 km S Paxton. 22 March 1969. R. Fetterolf.

Deirochelys reticularia miaria (Western Chicken Turtle): CHEROKEE Co. SFA-4645. New Summerfield. 21 April 1974. A Whitehurst. JASPER Co. SFA-2859. 1.6 km N Jasper. 1 April 1967. R. Dutcher. MARION Co. SFA-2612. Scottsville. 18 June 1966. L. Waite. NACOGDOCHES Co. SFA-4649. 14.5 km S Nacogdoches. 8 March 1974. R. Nicely. PANOLA Co. SFA-2611. Murval Creek. 12.9 km S Carthage. 18 June 1966. H. LaGrone.

Graptemys versa (Texas Map Turtle): SAN SABA Co. * SFA-4721, 4723, 4737, 4761, 4790. All five specimens collected on herpetology field trip from Rough Creek 16.1 km ESE San Saba. 22-23 April 1978.

Kinosternon subrubrum hippocrepis (Mississippi Mud Turtle): ANGELINA Co. * SFA-1284. NE city limits Lufkin. 3 July 1960. E. Dabbs. SFA-2927. U.S. 59 at Redland. 20 April 1967. J. Birch. JASPER Co. SFA-4696. Jasper State Fish Hatchery. 18 April 1975. W. Strelke. MARION Co. SFA-2435. Keener Ranch, Scottsville. 18 June 1966. L. Waite. NACOGDOCHES Co. * SFA-1197, 2433, 2866, 3013, 3108, 3416, 3583, 4697, 4783. These nine specimens are from various locations within the county and were collected from 1960 through 1978. TRINITY Co. SFA-2857. 9.6 km SW Groveton on TX. 94. 19 April 1967. R. Dutcher.

Macroclemys temmincki (Alligator Snapping Turtle): POLK Co. SFA-4600, (skull only). 1.6 km SE Goodrich, McCardle's Lake. 14 February 1973. C. Fisher.

Sternotherus carinatus (Razorback Musk Turtle): ANGELINA Co. * SFA-2860. Angelina River. 7 May 1967. R. Dutcher. CHEROKEE Co. SFA-1292. 9.6 km W Wells. 12 June 1960. J. Gaston. SFA-2436. 11.3 km S Alto on TX. 21. 4 July 1966. W. Holder. NEWTON Co. SFA-1563. Big Cow Creek. June 1960. J. Hurst.

Sternotherus odoratus (Stinkpot): ANDERSON Co. SFA-2316. 24.1 km E Palestine, Neches River. 18 October 1963. G. Lloyd. ANGELINA Co. * SFA-2438. 19.3 km S Nacogdoches at Angelina River. 2 July 1966. R. Garcia. SFA-2620. TX. 21 at Angelina River. 2 June 1966. M. Upshaw. MONTGOMERY Co. SFA-3764. 16.1 km SE Cleveland. 6 April 1969. J. Leach. NACOGDOCHES Co. SFA-2439. 4.8 km E Trawick. 6 June 1966. D. Shopay. SFA-4698. 4.8 km SE Nacogdoches. 16 April 1975. V. Suchy. SFA-4794. SFA Campus, Nacogdoches. 1 April 1978. G. Mowad.

Terrepene carolina triunguis (Three-toed Box Turtle): GREGG Co. SFA-1648. 11.3 km

E Kilgore. 22 October 1960. J. Kincaid. MARION Co. SFA-2627. Scottsville. 19 June 1966. L. Waite. PANOLA Co. * SFA-2624. 3.2 km SW Carthage on TX. 315. 22 June 1966. W. Gullette. SFA-2629. 16.1 km E Carthage. 20 June 1966. H. LaGrove. SAN AUGUSTINE Co. SFA-4862. 6.7 km NNW Broaddus. 24 April 1981. V. Rakowitz. SFA-4863. 9.7 km NNE Broaddus. 22 April 1981. V. Rakowitz. SMITH Co. SFA-2771. Tyler. 31 March 1967. W. Wilborn. VAN ZANDT Co. SFA-2970. 11.3 km N Canton. 22 April 1967. M. Robinson.

Terrepene ornata ornata (Ornate Box Turtle): FAYETTE Co. * SFA-3909. 4.8 km W Schulenburg. 12 April 1969. T. Frizzell. JEFFERSON Co. SFA-4404. 8 km E Fannet. 6 April 1969. M. Lewis. RED RIVER Co. SFA-3069. 8 km E Boxelder. 30 April 1967. C. Mather.

Trionyx muticus muticus (Midland Smooth Softshell): HUTCHINSON Co. SFA-3217. Lake Merideth. 5 August 1965. C. Mather. This record is a range-margin extension northwest from Gray Co. SHELBY Co. SFA-2836. 4.8 km E Tenaha. 22 April 1967. C. Nutt.

Trionyx spiniferus pallidus (Pallid Spiny Softshell): RUSK Co. SFA-1839. 22.5 km S Henderson, Lake Striker. June 1961. R. Adams.

SAURIA

Anolis carolinensis carolinensis (Green Anole): FREESTONE Co. SFA-2006, 2007. 9.6 km E Fairfield. 26 October 1962. R. Kiragon.

Cnemidophorus gularis (Texas Spotted Whiptail): RANDALL Co. * SFA-4357. 0.8 km E Palo Duro Canyon State Park. 7 April 1971. D. Wood.

Cnemidophorus sexlineatus sexlineatus (Six-lined Racerunner): ANGELINA Co. SFA-2427. 19.3 km S Nacogdoches at Angelina River and TX. 21. 2 June 1966. M. Upshaw. SFA-2428. Lufkin. 9 July 1966. A. Foley. NACOGDOCHES Co. * SFA-792, 793, 920, 1257, 1362, 1370, 1596, 1660, 1726, 2117, 2215, 3158, 3739, 3851, 3913. These fifteen specimens are from various localities within the county and were collected from 1959 through 1969. RUSK Co. * SFA-2051. 8 km E Henderson. 13 October 1962. V. Lewis. SFA-2908. 4.8 km W Henderson. 10 April 1967. J. Bynum. SABINE Co. SFA-3980. 24.1 km N Hemphill. 12 April 1969. B. McDowell. SAN AUGUSTINE Co. SFA-4872. 8.4 km NNW Broaddus. 8 April 1981. V. Rakowitz. *Cnemidophorus sexlineatus viridis* (Prairie-lined Racerunner): HEMPHILL Co. * SFA-1530. 4.8 km W Lake Marvin. 2 July 1960. G. Myers et. al. WEBB Co. * SFA-3779. Laredo. 6 April 1969. J. Leach.

Crotaphytus collaris collaris (Eastern Collared Lizard): CLAY Co. * SFA-3607. 4.8 km S Ryan, OK. 12 April 1969. B. Garrett.

Eumeces anthracinus pluvialis (Southern Coal Skink): MARION Co. SFA-5029. 3.2 km S Karnack. 15 April 1973. R. Jackson. SAN AUGUSTINE Co. SFA-4864, 4865. 7.6 km NNW Broaddus. 12 February 1981. V. Rakowitz. SHELBY Co. * SFA-1154. 6.4 km S Timpson. 23 April 1960. C. Cordes, R. Burkett.

Eumeces fasciatus (Five-lined Skink): SAN AUGUSTINE Co. SFA-4866. 1.6 km NNE Broaddus. 26 February 1981. A. Alexander. SFA-4867. 1.6 km NNE Broaddus. 14 April 1981. V. Rakowitz.

Eumeces laticeps (Broadhead Skink): SABINE Co. SFA-3978. 4.8 km S Hemphill. 12 April 1969. B. McDowell. SAN AUGUSTINE Co. SFA-4868. 1.6 km NNE Broaddus. 6 May 1981. V. Rakowitz.

Gerrhonotus liocephalus infernalis. (Texas Alligator Lizard): LLANO Co. SFA-4267. 9.6 km W Llano. 10 August 1969. J. Filecia.

Ophisaurus attenuatus attenuatus (Western Slender Glass Lizard): NACOGDOCHES Co. * SFA-364. Nacogdoches. 24 May 1958. J. Collins. SFA-3234. 6.4 km S Nacogdoches. 12 April 1967. C. Mather.

Phrynosoma cornutum (Texas Horned Lizard): LIMESTONE Co. SFA-2691. 3.2 km SE Tehuacana Post Office. 18 June 1966. A. Foley. NACOGDOCHES Co. * SFA-341, 790, 1179, 1181, 2261, 2262, 2401, 2476, 2695, 2701, 3055, 3254. These twelve specimens are from various localities within the county and were collected from 1958 through 1967. PANOLA Co. * SFA-1180. Carthage. 5 June 1960. W. Osborne. SABINE Co. SFA-1367, 1368. 4.8 km N Geneva. 14 June 1960. B. Simmons. These specimens represent the easternmost county record in Texas. This is a range extension eastward of 42 km from Nacogdoches Co. UPTON Co. SFA-4565. 19.3 km SE Crane. 28 March 1964. F. Brannowsky. VAN ZANDT Co. SFA-2957. 11.3 km N Canton. 25 February 1967. M. Robinson.

Sceloporus olivaceus (Texas Spiny Lizard): VICTORIA Co. * SFA-4073. Victoria. 4 April 1969. J. Vincent.

Sceloporus undulatus consobrinus (Southern Prairie Lizard): MIDLAND Co. SFA-3993, 3994, 3995. 48.3 km S Midland. 15 March 1969. T. Wenk. *Sceloporus undulatus garmani* (Northern Prairie Lizard): CHEROKEE Co. * SFA-1614, 2131, 2132, 2711. These four specimens were collected from separate localities within the county between 1960 and 1966. LAMAR Co. * SFA-870. 0.4 km N Paris. 27 October 1959. B. Coe SFA-871. 1.6 km N Paris. 28 October 1959. B. Coe. MORRIS Co. SFA-2195. 1.6 km E Dangerfield. 19 October 1962. S. Palmer. NAVARRO Co. SFA-2022. 1.6 km W Corsicana. 29 September 1962. R. Kiragon.

Scincella lateralis (Ground Skink): SAN AUGUSTINE Co. SFA-4869. 1.6 km NNE Broaddus. 16 April 1981. R. Fleet. SFA-4870. 3.3 km NE Broaddus. 16 April 1981. V. Rakowitz. SFA-4871. 7.6 km NNW Broaddus. 16 April 1981. J. deBin.

Urosaurus ornatus ornatus (Eastern Tree Lizard): COMAL Co. * SFA-4247. 32.2 km W San Marcos on FM rd. 12. 3 May 1969. G. Jacobs.

Uta stansburiana stejnegeri (Desert Sideblotched Lizard): MIDLAND Co. SFA-3651. 3.2 km S Midland. 6 April 1969. B. Garrett. SFA-4134. Midland. 6 March 1969. R. Fetterolf. The Midland County specimens represent a range-margin extension eastward from adjacent Ector County. UPTON Co. SFA-4260. 19.3 km E Crane. 28 March 1964. F. Bannowsky, E. Greding. This specimen represents a range-margin extension eastward from adjacent Crane County.

SERPENTES

Agkistrodon contortrix contortrix (Southern Copperhead): ANGELINA Co. SFA-340. 0.4 km N Pollock. 1 May 1958. J. Collins. NEWTON Co. * SFA-1881. 3.2 km N Farr's Chapel, near Big Cow Creek. 16 April 1961. J. Hurst. SFA-1970. 8 km N Burkeville. 8 September 1961. J. Hurst. COMAL Co. * SFA-4244. 27.4 km W San Marcos on FM rd. 12. 3 May 1969. G. Jacobs. This specimen was taken within the range of *A.c. laticinctus* as mapped by Conant (1975).

Agkistrodon piscivorus leucostoma (Western Cottonmouth): ANGELINA Co. SFA-2306, 2307. 3.2 km S Boykin Springs, Angelina National Forest. 18 June 1964. R. Murray. SFA-2429. 9.7 km W Lufkin on TX. 103. 1 June 1966. A. Foley. MARION Co. * SFA-2722. Keener Ranch, Scottsville. 5 July 1966. M. Land. PANOLA Co. SFA-1335. 6.4 km W, 3.2 km S Carthage. 29 June 1960. W. Osborne. SABINE Co. SFA-1355. Sabine River bottom near Hemphill. 1 June 1960. J. Phillips. UPSHUR Co. SFA-4779. 11.3 km W Gilmer. 18 March 1978. B. Reed.

Arizona elegans arenicola (Texas Glossy Snake): STARR Co. SFA-4406. 16.2 km N Rio Grande City on FM rd. 755. 23 May 1971. J. Jacob. *Arizona elegans elegans* (Kansas Glossy Snake): DONLEY Co. SFA-3192. 8 km W Hedley on U.S. 287. 3 September 1965. C. Mather.

Coluber constrictor anthicus (Buttermilk Racer): ANGELINA Co. * SFA-2322. 24.1 km S Nacogdoches. October 1964. R. Ireland. BRAZORIA Co. SFA-1586. Old Angleton Rd. between Angleton and Clute. 25 November 1960. C. Cordes. CHEROKEE Co. * SFA-1301. 8 km W Wells. 13 June 1960. J. Gaston. NEWTON Co. * SFA-1885. 1.6 km NW Newton. 14 May 1961. J. Hurst.

Coluber constrictor flaviventris (Eastern Yellowbelly Racer): GRAY Co. SFA-3165. Lake McClellan. 24 June 1965. C. Mather. LAMAR Co. SFA-874. 1.6 km N Paris. 28 October 1959. B. Coe.

Crotalus atrox (Western Diamondback Rattlesnake): KENT Co. * SFA-302. 32.2 km S Snyder. 5 April 1958. J. Collins.

Diadophis punctatus arnyi (Prairie Ringneck Snake): SAN SABA Co. SFA-4736. 16.1 km SE San Saba, Rough Creek. 21 April 1978. C. Hodgson.

Drymarchon corais erebennus (Texas Indigo Snake): DUVAL Co. * SFA-4329. 12.9 km NE Freer on U.S. 59. 20 June 1970. W. Dickens.

Elaphe guttata emoryi (Great Plains Rat Snake): BELL Co. SFA-4352. 9.7 km S U.S. 190 on FM rd. 1670. 8 May 1970. D. Wood.

Elaphe obsoleta lindheimeri (Texas Rat Snake): ANGELINA Co. * SFA-1281, 2442, 3283. These three records are from different localities within the county and were collected in 1960, 1966, and 1967, respectively. JASPER Co. * SFA-2893. Jasper. 2 April 1967. J. Talbett. LIBERTY Co. * SFA-2444. 8 km W Hardin. 1 June 1966. H. Baker. NACOGDOCHES Co. * SFA-717, 1103, 2310, 2323, 2440, 2752, 3028, 3107, 3286, 3601, 3895. These eleven records represent collections from various localities within the county from 1957 through 1969. SAN AUGUSTINE Co. * SFA-4873. 7.6 km NNW Broaddus. 12 April 1981. J. deBin.

Farancia abacura reinwardti (Western Mud Snake): NACOGDOCHES Co. * SFA-1216, 1233, 2033, 2309, 4673. These six specimens

are from different locations within the county and were collected from 1960 through 1974.

Heterodon platyrhinos (Eastern Hognose Snake): ANDERSON Co. SFA-2150. 4.2 km from Neches River in Neches Oil Field. 20 October 1962. R. Lanier. ANGELINA Co. * SFA-1278. 4.8 km NW Lufkin on old Moffitt Rd. 20 June 1960. E. Dabbs. CHEROKEE Co. * SFA-2125. Price's Switch on Neches River. 28 September 1962. R. Lanier. GREGG Co. SFA-3836. 3.2 km S Lakeport on TX. 322. 15 April 1969. D. Wilkinson. JASPER Co. * SFA-3045. 16.1 km N Vidor. 29 March 1967. B. Bilbo. NAVARRO Co. * SFA-2168. Kerens. 3 November 1962. D. Baker. SHELBY Co. * SFA-907, 1302, 1344, 1703, 1706. The five specimens came from different locations in the county and were collected in 1959 and 1960. WOOD Co. * SFA-1222. 1.6 km SE Mineola, Smith Creek. 11 June 1960. J. Bruner.

Lampropeltis calligaster calligaster (Prairie Kingsnake): NAVARRO Co. SFA-1635. Corsicana. 22 November 1960. K. Kimes. SFA-2944. 19.3 km W Corsicana on TX. 31. 2 April 1967. J. DeFranco. RUSK Co. Lampropeltis triangulum amaura (Louisiana Milk Snake): NEWTON Co. * SFA-1503. 6.4 km N Bon Wier. 8 October 1960. J. Hurst. POLK Co. SFA-4339. Shore of Lake Livingston. 14 June 1970. J. Vincent and T. Brannon.

Masticophis flagellum flagellum (Eastern Coachwhip): NACOGDOCHES Co. * SFA-815, 882, 896, 2948, 3025, 3111. The six specimens are from several locations within the county and were collected from 1959 through 1967. RUSK Co. SFA-2161. 8 km E Henderson. 13 October 1962. R. Kiragon. SFA-2466. 6.4 km W Tatum. 15 June 1966. L. Jameson. SAN AUGUSTINE Co. SFA-4876. 8.4 km NNW Broaddus. 8 May 1981. V. Rakowitz. *Masticophis flagellum testaceus* (Western Coachwhip): MIDLAND Co. SFA-3600. 12.9 km S Midland. 7 April 1969. B. Garrett.

Micrurus fulvius tenere (Texas Coral Snake): LAMAR Co. SFA-873. 1.6 km N Paris. 28 October 1959. B. Coe. This record is a range extension of 83 km northwest from the nearest county record in Morris County. SAN AUGUSTINE Co. SFA-4877. 3.3 km NE Broaddus. 12 April 1981. V. Rakowitz.

Nerodia cyclopion cyclopion (Green Water Snake): FORT BEND Co. SFA-2822. Jew's Prairie. 28 March 1967. C. Meitzen.

Nerodia erythrogaster flavigaster (Yellowbelly Water Snake): ANGELINA Co. * SFA-2810. Sam Rayburn Lake. 14 April 1967. S. Fleener. CHEROKEE Co. * SFA-601, 1289, 2103, 2154, 2456. The five specimens were collected from several localities within the county from 1938 through 1966. NACOGDOCHES Co. * SFA-318, 602, 1188, 1201, 1381, 2753, 3019, 3579, 3869, 4230. The ten specimens were collected from various locations in the county from 1938 through 1969. NEWTON Co. * SFA-714. 16.1 km E Burkeville. 12 April 1957. E. Toole. PANOLA Co. SFA-1332, 1333, 1334. 6.4 km W, 3.2 km S Carthage. 29 June 1960. W. Osborne. ROCKWALL Co. SFA-3723. S shore Lake Ray Hubbard. 1 March 1969. K. Weatherford. VAN ZANDT Co. SFA-2966. 1.3 km N Canton. 8 April 1967. M. Robinson. *Nerodia erythrogaster transversa* (Blotched Water Snake): POTTER Co. * SFA-3167. Canadian River, 24.1 km N Amarillo, U.S. 287. 17 July 1965. C. Mather.

Nerodia fasciata confluens (Broad-banded Water Snake): ANGELINA Co. SFA-1271. 0.8 km NE Lufkin. 9 June 1960. E. Dabbs. CHEROKEE Co. SFA-1300. 8 km W Wells. 13 June 1960. J. Gaston. SFA-1941. 11.3 km NW Rusk. 18 June 1962. C. McClatchey. WALLER Co. SFA-2609. Lake Winona. 2 July 1966. L. Waite. WILLIAMSON Co. SFA-3085. San Gabriel River, Georgetown. 22 April 1967. M. Watkins. This specimen represents a range-margin extension north from adjacent Travis County.

Nerodia rhombifera rhombifera (Diamondback Water Snake): CHEROKEE Co. * SFA-2145. Lake Jacksonville. 5 October 1962. R. Lanier. FREESTONE Co. SFA-2036. Hill Ranch, Fairfield. 20 October 1962. R. Kiragon. NACOGDOCHES Co. * SFA-1862, 1991, 2025, 2311, 2454, 2754, 2874, 3239, 3361, 3724. These ten specimens were collected from various locations within the county from 1961 through 1969. SAN AUGUSTINE Co. * SFA-4878. 3.3 km NE Broaddus. 12 April 1981. V. Rakowitz. VAN ZANDT Co. SFA-2967. 11.3 km N Canton. 8 April 1967. M. Robinson.

Opheodrys aestivus (Rough Green Snake): ANDERSON Co. SFA-2151. 3.9 km from Neches River in Neches oil field. 6 October 1962. R. Lanier. ANGELINA Co. SFA-1275. 1.6 km NW Lufkin. 18 June 1960. E. Dabbs, SFA-2606. Lufkin. 15 June 1960. A. Foley. GREGG Co. SFA-2202. Rabbit Creek. 8 October 1962. C. Burrow. KAUFMAN Co. SFA-3690. 9.7 km N Kaufman. 4 April 1969. K. Skidmore. NACOGDOCHES Co. SFA-1814. 12.9 km E Nacogdoches. 6 July 1961. E. Caldwell. SFA-4760. Nacogdoches. 28 March 1978. M. Stafford. PANOLA Co. SFA-1329. 6.4 km W, 3.2 km S Carthage. 29 June 1960. W. Osborne. SFA-2372. 16.1 km SE Carthage. 22 October 1964. W. Gullette. SFA-2463. 19.3 km E Carthage. 20 June 1966. H. LaGrone. POLK Co. * SFA-2336. 3.2 km E Corrigan. 29 October 1964. R. Chisolm.

Pituophis melanoleucas ruthveni (Louisiana Pine Snake): WOOD Co. * SFA-5038. 30.6 km NW Gilmer. 26 May 1973. D. McKee. This specimen confirms an isolated literature record for the county and is 330 km north of the northernmost Texas population records. *Pituophis melanoleucus sayi* (Bullsnake): GRAY Co. * SFA-3193. Lake McClellan. 17 August 1965. C. Mather. GRAYSON Co. SFA-4669. 10.5 km W intersection of FM rd. 1417 and U.S. 82. 25 March 1975. R. Hendricks. This specimen is a link between the isolated Fannin County record and the more westerly records.

Regina grahami (Graham's Crayfish Snake): CHAMBERS Co. SFA-4613. 11.3 km S Winnie on TX. 124. 5 April 1974. R. Beavers. NACOGDOCHES Co. SFA-3915. 19.3 km S Nacogdoches near Angelina River. 28 April 1969. T. Frizzell. This specimen is from the East Texas area hitherto devoid of county records for this species.

Regina rigida sinicola (Gulf Crayfish Snake): CHEROKEE Co. SFA-1942. 11.3 km NW Rusk. 18 June 1962. C. McClatchey. NACOGDOCHES Co. SFA-2143. 8 km E Nacogdoches. 13 October 1962. R. Lanier. SFA-3908. Nacogdoches. 11 April 1969. T. Frizzell. The Cherokee and Nacogdoches County records fill the hiatus between Rusk and Smith Counties to the north and Angelina County to the south.

Rhinocheilus lecontei tessellatus (Texas Longnose Snake): POTTER Co. SFA-3159. N city limits of Amarillo. 18 August 1965. C. Mather. This record bridges the gap between Randall County to the south and Hutchinson County to the northeast.

Sistrurus catenatus tergeminus (Western Massasauga): ARCHER Co. SFA-4881. 4.8 km N Lake Kickapoo. 14 June 1968. E. Roth. SFA-4882. Lake Kickapoo. 30 June 1968. W. Seifert. SFA-4883. 8 km E Lake Kickapoo. 22 April 1970. W. Seifert.

Sistrurus miliarius streckeri (Western Pigmy Rattlesnake): NACOGDOCHES Co. SFA-4586. 16.1 km S Nacogdoches. 21 August 1972. R. Jackson. SFA-4587. 8 km NE Nacogdoches. 24 February 1973. M. Garrett. SABINE Co. SFA-3979. 4.8 km S Hemphill. 12 April 1969. B. McDowell. SAN AUGUSTINE Co. SFA-4879. 4.1 km NE Broaddus. 4 May 1981. M. Whiting.

Sonora episcopa taylori (South Texas Ground Snake): ZAPATA Co. * SFA-4088. Falcon State Park. 5 April 1969. J. Vincent.

Storeria occipitomaculata occipitomaculata (Northern Redbelly Snake): CASS Co. SFA-5024. 11.3 km N Atlanta. 14 April 1973. R. Hendricks.

Storeria dekayi texana (Texas Brown Snake): SMITH Co. SFA-2326. Tyler. 15 October 1964. R. Moss.

Tantilla gracilis (Flathead Snake): HENDERSON Co. SFA-1058. 8 km SW Malakoff. 7 April 1958. W. Robertson.

Tantilla nigriceps fumiceps (Texas Blackhead Snake): HOCKLEY Co. SFA-4599. 2.4 km N Levelland. 20 July 1972. J. Schultz. This record is a range-margin extension westward from adjacent Lubbock County.

Thamnophis proximus proximus (Western Ribbon Snake): ANGELINA Co. SFA-1274. 0.8 km NE Lufkin. 17 June 1960. E. Dabbs. SAN AUGUSTINE Co. SFA-4880. 8.4 km NNW Broaddus. 12 April 1981. V. Rakowitz. WOOD Co. SFA-2465. 24.1 km E Quitman on TX. 154. 25 June 1966. D. Seago.

Thamnophis sirtalis annectans (Texas Garter Snake): SAN PATRICIO Co. SFA-3695. 11.3 km N Sinton. 19 April 1969. K. Skidmore.

Tropidoclonion lineatum annectens (Central Lined Snake): CHEROKEE Co. SFA-1834. 4.8 km N Rusk on U.S. 69. 1 July 1961. V. Barton. SMITH Co. SFA-2733. 4.0 km E Tyler

on U.S. 59. 27 March 1967. M. Vredenburg. The Cherokee and Smith County records constitute successive range-magin extensions southward from Gregg County. This results in a range extension southward of 65 km.

Virginia striatula (Rough Earth Snake): HOUSTON Co. SFA-3156. Crockett. 12 February 1967. C. Mather. SFA-3218. 6.4 km W Crockett on FM rd. 2026. 25 March 1967. C. Mather. NACOGDOCHES Co. * SFA-71, 298, 653, 2873, 2901, 3086, 3548, 3604, 3727, 3923. These ten specimens were collected from several localities within the county from 1957 through 1969.

Virginia valeriae elegans (Western Earth Snake): GREGG Co. SFA-266. 16.1 km SE Longview. 19 January 1958. G. Raney. This record is a range-margin extension northeast from adjacent Rusk County.

BOOK REVIEWS

Threatened Amphibians and Reptiles in Europe, by Rene E. Honegger. Academische Verlagsgesellschaft (Postfach 11 07, D-6200 Wiesbaden, West Germany) 1981, 158 pp, cloth bound, boxed, DM 68, ISBN 3-400-00437-5.

This small book is a supplementary volume of the "Handbuch der Reptilien und Amphibian Europas" and was edited by the European Committee for the Conservation of Nature and the Natural Resources-Council of Europe. This well-bound, attractively printed book is marred by numerous typographical errors.

Dr. Rene E. Honegger of the Zurich Zoo has been active in the conservation of European amphibians and reptiles for more than a decade. Working with numerous colleagues he has now produced an "official" guide to the threatened species of the European herpetofauna. Each of 14 taxa of amphibians and 39 of reptiles considered to be threatened are documented in detail, including status (extinct, endangered, vulverable, rare, or undetermined), distribution, populations in Europe, habitat, reasons for decline, conservation measures taken, conservation measures proposed, and remarks.

These accounts are documented thoroughly. For example, the olm *(Proteus anguinus)* is noted as having been introduced from Yugoslavia to the Parolini Grotto in Italy about 1850; among the reasons for the decline of the species is the habit of farmers collecting them for pig food. Likewise, the decline of island populations of lacertid lizards is documented — *Podarcis filfolensis* because island shelled by British Navy for target practice, *Podarcis lilfordi rodriguezi* because habitat destroyed in the rebuilding of a port, *Podarcis lilfordi lilfordi* and *Podarcis sicula coerulea* because of over-collecting.

The first third of the book is devoted to the reasons for decline and protective measures. Honegger concludes that the main reason for the drastic decline of the European herpetofauna is habitat destruction. He provides extensive documentation of habitat destruction and diminution of populations, especially the draining and filling of wetland habitats and the detrimental effects on populations of amphibians. Second in importance is chemical effects (pesticides, acidification, and pollution), followed by collecting and trade, and lastly, effects of introduced species.

American herpetologists will recognize equivalent problems of habitat destruction and chemical effects in North America. However, Americans will be appalled at the numbers of amphibians and reptiles collected for the pet trade and culinary purposes in Europe. For example, on the basis of weight of exports, Honegger estimates that more than 2 million frogs were exported from Greece in 1975 alone; these were for human consumption. Data for specimens collected in Italy in 1968-1970 for commercial, scientific, and culinary purposes amounted to more than 235,000 reptiles, 96,000 salamanders, and more than 47 million frogs, most of the latter for food. The pet trade of amphibians and reptiles flourishes in Europe more than anywhere else in the world. Some of the persons that purchase and maintain amphibians and reptiles make careful observations that result in worthwhile contributions to the scientific literature as published in numerous aquarium and terrarium journals, but the vast majority of animals must be wasted. I suspect that a very small percentage of the total number of specimens collected are destined for scientific endeavors; yet because of the necessity of protective regulations, scientists who have legitimate research needs are restricted by regulations aimed at commercial interests.

In the chapter on protection, the major issues are discussed and the existing and proposed legislation in Europe and in each country is summarized. Protection varies from all species of amphibians and reptiles being nominally protected by law in Denmark, France, Gibraltar, Lichtenstein, Luxembourg, and the Netherlands, to no protection in Greece, Norway, and Turkey. Honegger emphasizes eight aspects of conservation of the herpetofauna; 1) Conservation of habitats (main aspect); 2) Management and creation of habitats; 3) Legal conservation of taxa; 4) Restriction against the use of pesticides and measures against pollution; 5) Education of the decision makers and general public; 6) Coordination of conservation efforts among conservationists, ecologists, legal authorities, and the general public; 7) Measures to eliminate traffic mortalities; and 8) Intensification of basic and practical research.

Europeans are well ahead of other parts of the world in conservation efforts. This is evident from the existence of the book under review. Why doesn't a comparable volume exist for North America? Persons interested in the survival of amphibians and reptiles in their native habitats will find this book useful and enlightening while being discouraging at the same time. Persons involved in gathering data for conservation measures and proposing legislation will find the documentation and extensive bibliography pertaining to European species as a useful guide. And may everyone who eats frog legs from Greece and Italy suffer acute indigestion.

Tortues Marines de Guyane, by Jacques Fretey. 1981. 136 p., 114 photos (18 color), soft cover (8-3/4 x 9-1/4 in.). Publisher and source: Editions du Léopard d'Or, 11 rue du 4-Septembre, 75002 Paris, France (cite ISBN 2.86377.008-X). Price: 140 French francs including surface post (airmail 25 francs extra).

French Guiana, situated between Surinam and Brazil on the northeastern coast of South America, has some of the prime nesting beaches for sea turtles. Beginning in 1978 the World Wildlife Fund initiated a project to study and protect sea turtles along the French Guiana coast, under the supervision of Jacques Fretey, zoologist with the Museum National d'Histoire Naturelle in Paris since 1973. This handsome book, which includes a large number of beautiful photographs mostly by the author, is an important contribution to our knowledge of the five species found there: *Chelonia mydas, Lepidochelys olivacea, Caretta caretta, Eretmochelys imbricata,* and *Dermochelys coriacea.*

Following a brief historical summary and an illustrated key to species, there are short sections on osteology and anatomy and mating behavior. There are extensive discussions (with detailed maps and photos) of nesting areas in French Guiana, movement patterns of females on the beaches, egg-laying behavior, mortality of adults, incubation of eggs, emergence, predation on hatchlings (including fish, dogs, coatimundi, crabs and, especially, birds), the influence of tourists, and a short discussion of Fretey's tagging program. Finally, there is a summary of some of the measures taken to protect the sea turtles and their nesting beaches in French Guiana (including photos of conservation posters displayed there) and a final chapter on representations of sea turtles in the pottery and carvings of the local Kaliña Indians.

This is an excellent first attempt to popularize these remarkable animals in French Guiana and to develop a greater appreciation by the general public of the importance of the nesting areas there. Let us hope that the book will have the desired effect, to reverse the sad decline of sea turtle populations, especially for the leatherback for which the French Guiana beaches represent one of the best nesting areas in the world.

Herpetology of Africa: A Checklist and Bibliography of the Orders Amphisbaenia, Sauria, and Serpentes, by Kenneth R. G. Welch. 1982. 314 pages. $19.50. Robert E. Krieger Publishing Company, Inc., PO Box 9542, Melbourne, Florida 32901, USA.

It is remarkably easy to find fault with checklists, in part because they frequently carry opinions other than our own, but more fundamentally because the difficulty in preparing any worthwhile checklist precludes perfection. This particular checklist is not perfect, but it is worthwhile and should be a welcome addition to the bookshelf of any herpetologist who wants easy access to the literature of the reptiles of Africa, Madagascar, and adjacent islands.

The title printed on the front cover of the book, *Herpetology of Africa,* is misleading because this volume does not treat amphibians and treats adequately only the squamates; the turtles and crocodilians are given short shrift. Within the squamates Welch provides current generic, species, and subspecies names, each with the author and year proposed. Type species are provided with the genera and distributions are given for species and subspecies. The stated distributions tend to be too general. For those species and subspecies that were described under a different generic name the original name is given at the margin to the right of the current name. These marginal notations might be confusing because this convention is explained nowhere in the text. Each genus, species, and subspecies record includes citations to pertinent literature. To my knowledge, all literature cited, both original descriptions and other reference literature, appears in the bibliography, although such bibliographic anomalies such as Tornier, 1900a, but no 1900b makes one wonder. Diacritical marks are not used in this volume, a minor problem, but a little annoying when Günther is spelled Gunther rather than the correctly transliterated Guenther. I know of only one species missed by Welch, *Python saxuloides* Miller and Smith, 1979 (Bull. Maryland Herp. Soc. 15:71), an oversight forgivable given the recency and obscurity of the description.

The crocodilians and turtles are treated somewhat inadequately, especially considering their small numbers. Only a list of current taxonomy, names and authors is provided in an appendix, with no distributions. All reference to pertinent literature is presented at the beginning of each order. In another appendix familial references are provided; these references would have been better placed in the body of the checklist. Another appendix references regional works and may be useful to those interested in faunal surveys.

Welch has treated nearly 1700 species and provided 1600 references in this volume. This represents a great deal of work on the part of Welch and a great deal of work saved for those interested in African herpetology. In spite of a few relatively minor problems, $19.50 is a small price to pay for ready access to the literature on African reptiles.

Philippine Lizards of the Family Gekkonidae, by Walter C. Brown and Angel C. Alcala. Dumaguete City; Silliman University (Natural Science Monograph Series No. 1). 1978. 146 pages.

Philippine Lizards of the Family Scincidae, by Walter C. Brown and Angel C. Alcala. Dumaguete City; Silliman University (Natural Science Monograph Series No. 2). 1980.

The team of Brown and Alcala has a remarkable record of steady production of useful contributions to our knowledge of the Philippine herpetofauna. These two volumes cover the two principal families of lizards in the Philippine Islands — 32 species of gekkonids and 64 of skinks. The other families, Agamidae, Varanidae and Dibamidae combined, are represented in the Philippines by only 15-25 species.

Both volumes continue the tradition of care and attention to detail that characterizes the work of these authors. Each volume begins with a key to genera followed by a section on each genus and ending with a discussion of zoogeographic phenomena. Each generic segment consists of a key to the species and for every species a complete synonymy, lists of material examined, complete description, range, and ecological notes. The tables of scale counts and measurements are scattered through the volumes. Both line drawings and half-tone illustrations are included.

A few technical details mar these otherwise excellent monographs. In general, the halftones are not clear and, therefore, not very useful. The line drawings of the gekkonid volume are fine but some of those of the scincid one are too small to be helpful. There is also a disturbing number of typographical errors, only a portion of which is noted in errata sheets. The most troublesome ones involve incorrect notation of figure numbers in several keys. Fortunately, all these mistakes are easily caught and rectified by anyone with a serious interest in the subject matter.

The diversity and endemism of these two families in the Philippines are impressive and do not appear to be based on excessive splitting. Each family is represented by 10 genera. Seventy-two percent of the gekkonid species and 81% of the skinks are endemic. Brown and Alcala speculate that their list of species of gekkonids is probably close to the actual number occurring in the Philippines except possibly for forms restricted to very small islands. That seems to be a reasonable estimate. The list of skinks is certainly incomplete. That Palawan is known to be poorly explored makes it likely that the 10 species now recorded from there represent less than half of the actual number.

One bit of interesting information is buried in the volume on geckos. *Hemidactylus frenatus,* one of the most cosmopolitan of house geckos, is rarely encountered in forests (even secondary ones) in Southeast Asia and Borneo. Yet Brown and Alcala observe that it is abundant in ". . . all natural tree-vegetation types up to about 400 meters." *Gekko monarchus,* known only from houses and other man-made environments in the Malay Peninsula and Borneo, is according to Brown and Alcala apparently more abundant in forests in the Philippines than in man's neighborhood. What enables these inquilines of man to exploit the forest environment in the Philippines?

Brown and Alcala emphasize that we lack information on the basic biology of most of the species covered. Fortunately, these volumes provide a springboard for local biologists who wish to study the natural history of Philippine geckos and skinks. They also pro-

vide a wealth of information for taxonomists working on these two families.

These books may be purchased from the Department of Herpetology, California Academy, San Francisco, California 94118 or from the Division of Research and Development, Silliman University, Dumaguete City 6501, Negros Oriental, Philippines. The price of the gekkonid volume is $6.00 and of the scincid volume $8.00.

ROBERT F. INGER
Field Museum of Natural History ●

Handbuch der Palaeoherpetologie. Part 2. Gymnophiona, Caudata by R. Estes. 1981. Gustav Fischer. 131p illust. DM 138.

All known specimens of fossil Caudata and Gymnophiona are included in this number of the Handbuch. Each specimen is illustrated and accurately described. Estes summarizes the geological and geographic distribution of the fossils but has to admit that the available material does not yet provide an answer to the origin of salamanders nor for the caecilians either as only one fossil is currently recognized as belonging to that group. This volume is only one part of a projected 19-part series. ●

Snakes of Virginia, by Linzey, D. W. and M. J. Clifford. 1981. Univ. Press of VA., Charlottsville. xiv + 159p. illust. $15.95.

The Snakes of Virginia provides for each species a description of adult and young, the habitat, geographic range, notes on habits and reproduction, on longevity, food, enemies, and location of museum specimens. A map shows the state distribution by counties. There are keys for the identification of species, handsome color plates, and an extensive bibliography. This will be a most useful handbook for Virginia snake enthusiasts. ●

The Journal of Oman Studies. Special Report no. 2. The Scientific Results of the Oman Flora and Fauna Survey 1977 (Dhofar). 1980. 399p. illust. obtainable from the Ministry of National Heritage and Culture, PO Box 668, Muscat, Sultanate of Oman. 20 pounds.

The Journal is a beautifully printed book that contains a variety of articles on the flora and fauna of Oman. It is lavishly illustrated with numerous figures and plates, among which are color plates of butterflies, acridodean grasshoppers, birds, etc. Of interest to herpetologists are: "The reptiles and amphibians of Dhofar, Southern Arabia" by E. N. Arnold, "Chromosome morphology of some reptiles from Oman and adjacent territories" by W. R. Branch, as well as in-depth descriptions of the ecology and general environment of Dhofar. A fold-out map identifies the localities mentioned in the 22 articles. The Sultan of Oman is to be congratulated for making this splendid contribution about his country available to all of us.

Missouri's Venomous Snakes (1981). Missouri Department of Conservation, Natural History Section, P.O. Box 180, Jefferson City, Missouri 65102, $35.00.

This is an audiovisual program consisting of 78 transparencies and a cassette tape lasting 14.4 minutes. The program was written by Tom R. Johnson, who was also responsible for most of the photography and all of the line drawings. Others credited with photos are Carl Gerhardt, Mark Sullivan, Gordon Maupin, John Wylie, and Joel Vance. Tom Troughton was responsible for sound. The narration is by Jim Keefe. The pictures are of the high quality we have come to expect of Johnson after *The Amphibians of Missouri* (Johnson, 1977) and a previous audiovisual program, *Voices of Missouri's Toads and Frogs* (Johnson, 1979; see Villa and Powell, 1980, for review). The narration is clear and well modulated. In all, the package is professional and certainly worth its price. Both Johnson and the Missouri Department of Conservation should be commended.

The program begins with several introductory comments on venomous snakes, common attitudes toward them, and the harmless, even beneficial, nature of snakes in general. This is followed by a short and interesting discourse on the distinction between the terms venomous and poisonous. The next section introduces Missouri's venomous species, explains how to distinguish them from harmless species, discusses the nature and composition of venoms, emphasizes the often beneficial predatory role these snakes play, and lists animals that may in turn prey upon the snakes. Each species is then covered in a more detailed sequence. Brief comments deal with the size and distinguishing characteristics of the species, its habitat and range within the state, and the potential severity of its bite. In addition, some accounts include notations of food preferences and habits. Several also illustrate and discuss the differences of non-venomous species with which the snake in question is often confused. A short section dealing with the prevention of snakebite is followed by an even briefer section on first aid treatments. A summary emphasizes that enjoyment of the out-of-doors need not suffer due to the presence of potentially dangerous snakes, and may actually be enhanced by it. Credits and a final, humorous slide conclude the program.

Comparisons may be odious, but are often necessary; comparing the *Venomous Snakes* program with its predecessor, *Voices of Missouri's Toads and Frogs*, is inevitable. There are 15 more slides in *Snakes* than in *Voices*; and there is a general technical superiority in the slides themselves. For example, slides with inserts (a habitat photo with an insert of the snake in question) and composite slides, made of up to six photographs, are included. There are also photos of food items (a lizard, a fish) and some that, though not directly relevant to the "core" of the program, enhance its aesthetic value (a fisherman posed against a sunset, a hiker, and a child holding a snake).

Some of the extra slides, however, are a bit too much. The Information Section of the Department, which put the package together, could have easily trimmed some without affecting the program. There are, for example, seven slides of titles and acknowledgements at the beginning and end of the program; these could have been reduced to two or three and still provide the same information. There are three pictures of a technician in nearly identical poses to illustrate lab work on venoms. There are some snakes pictured by two or three slides, some apparently of the same individual (the Osage copperhead, western pygmy rattlesnake, and timber rattlesnake), while another subspecies, mentioned and mapped, is not pictured (the southern copperhead). There are also slides of a mouse, a bee, a mushroom, the covers of two pamphlets, and even a set of car keys (have them handy to take a snakebite victim to the hospital!) which add little but dollars to the cost of the program ($10 more than *Voices*).

There is artwork, some in color, to illustrate a few points. We have seen Johnson's drawings, frequently appearing in *Herpetological Review* as well as in his own publications, and find those in *Snakes* a disappointment. Poor quality reproductions may contribute to this.

One topic is disconcertingly misplaced. The rattlesnake's rattle is not described until after three subspecies of *Sistrurus* have already been noted to possess a rattle. On the other hand, there is a good recording of a timber rattler's buzz, probably the only one most Missourians will ever hear.

We feel the inclusion of the distributional record of the cottonmouth in northern Missouri (Livingston County) is questionable. While the record is noted as being old, it most likely is no longer valid. Its presence merely increases the possibility of mistakenly identifying water snakes as being venomous in an area where this is, at best, unlikely.

The packaging of the products is also somewhat different. *Voices* comes with a cassette tape of adequate length, identically recorded on both sides, making rewinding unnecessary. The Information Section recorded *Snakes* on only one side, where it occupies less than half the tape available. The rest is blank.

Our major criticism, however, is the obvious ambivalence regarding the audience to whom the program is directed. If directed to an elementary or secondary school-age audience, the material dealing with the snakes themselves, snakebite prevention, and attitude are excellent. Those dealing with snakes as predators and with animals that prey on snakes are good, but should be expanded, as should the notations of relationships between these snakes and their environments. The portion of the program covering venoms and their compositions is extraneous and disconcertingly out of place; it is potentially confusing and even the photos detract from the continuity of the presentation. Similarly, the section mentioning first aid contributes little and

would best be omitted altogether. On the other hand, if the program is directed to a more advanced audience, undergraduates or even professional herpetologists, the introductory and summary comments are overly simplistic and often superfluous. The species accounts cry out for a more formal approach, at least the inclusion of generic and trivial names and a brief mention of systematic relationships. An expansion of those notations dealing with ecological topics would be necessary. More detailed explanations and relevant illustrations should be incorporated into the section on venoms, or it should be omitted. Johnson informed us that legal implications prohibited in-depth coverage of first aid treatment. Omission would have been preferable to citing a single source, the American Red Cross, whose suggested treatment has undergone frequent and significant revisions in recent years. The inclusion of a section dealing with clinical treatment by medical professionals, though similarly prohibited, would also be valid and would further expand the potential audience to include physicians and hospital emergency room personnel, whose knowledge of this topic is unfortunately often lacking. With proper treatment being a matter of much controversy, discussion of alternatives and their advantages and disadvantages would add significantly to the program.

In spite of our complaints, the program is serviceable and meets a need in expanding the public's understanding of venomous snakes. Also, its relatively low cost enhances its chances of being incorporated into the educational curricula of elementary and secondary schools, scouting and community service programs, and even colleges like ours, which lack extensive specimen collections, tape and slide libraries, as well as the funds to develop them. So, while encouraging Johnson and the Missouri Department of Conservation to develop alternate versions of the program oriented to different audiences, we nevertheless applaud their efforts in producing *Missouri's Venomous Snakes* and encourage other states to follow suit in using this means of educating the public.

Silver Anniversary Year 1958- 1982 Membership Directory Of The Society For The Study Of Amphibians And Reptiles

The first comprehensive listing of the membership of the society now numbering over 2,000 professional and amateur herpetologists. This directory will also include a brief history of the society, the constitution and bylaws, a listing of all previous society officers and annual meeting sites, and a listing of worldwide herpetological societies and organizations and their publications prepared by the 1982 Regional Society Liaison Committee.

To Order:

Send $4 payable to SSAR.

The directory will be in the same style and size as the *Journal of Herpetology* for easy binding. Commercial use of the list will not be permitted. Prices include packing and shipping. Address orders to Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056 U.S.A. Receipt sent on request only. Mark here ☐ if you wish to have a complete pricelist of SSAR publications including the *Journal of Herpetology, Facsimile Reprints in Herpetology, Herpetological Review, Herpetological Circulars, Catalogue of American Amphibians and Reptiles,* and the publications of The Ohio Herpetological Society.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

"THE SNAKE," THE JOURNAL PUBLISHED BY THE JAPAN SNAKE INSTITUTE

Japan Snake Institute is a non-profit scientific organization founded in 1968. The Institute covers a total area of 21000 m^2 with building space covering 2000 m^2, including laboratories, museum, three warm rooms and ten outdoor enclosures for live snakes. Okinawa Branch Laboratory was constructed in Tamagusuku Village in May, 1977.

The purpose of the Institute is breeding and ecological studies of snakes of domestic and foreign countries, studies on snake venoms, and treatment and prophylaxis of snakebite. In addition to this scientific research, exhibition of snakes and demonstration of extraction of venoms are held for general education of the public.

Since 1969, "The Snake," journal of the Institute, is published two issues per year for the purpose of dissemination of work carried out in the Institute and other related research organizations in the tropical areas. In 1982, Vol. 14, No. 1 and 2 were published. Subscription rate for "The Snake," including overseas postage is US$20.00 per two year base. Back issues are also available. Individuals or institutions desiring to subscribe should write to the Japan Snake Institute, Yabuzukahonmachi, Nittagun, Gunma 379-23, Japan. ●

ST. LOUIS HERPETOLOGICAL SOCIETY

The St. Louis Herpetological Society is a group of amateur and professional herpetologists dedicated to promoting the appreciation and conservation of our diverse herpetofauna, especially that of Missouri. The society is a non-profit organization and was founded in 1974.

The organization meets in the Community Room of the Greensfelder Recreation Complex at Queeny Park, 550 Weidman Road, Manchester, Missouri. Meetings begin at 7:00 PM and are held on the second Sunday of each month; there are no meetings during the months of June, July and August. Meetings include a guest speaker or presentation, an organized business meeting and good fellowship among members and guests.

Membership in the SLHS is for the calendar year, *i.e.*, from January 1 to December 31 of each year. Members who agree to join the society any time during the year will receive all back issues of publications for that year and then continue receiving them as they are published. Dues for each calendar year are payable as early in January as possible. Membership categories are: Individual — $7.00; Family — $10.00; Overseas — $15.00.

The society's basic means of public education is by publication of our newsletter, containing information, news items, and other matters regarding herps. We depend largely upon our membership for these contributions to the newsletter. The SLHS Newsletter is published approximately 10 times per year, and is usually 5 pages or more in length.

The SLHS also maintains a speakers bureau, which gives slide presentations and lectures on Missouri's herpetofauna to interested groups. Public education, along with donations to conservation groups and to the St. Louis Zoo Parents Association, contributes to conservation and protection of our reptiles and amphibians. A poster, "Please ... Don't Kill That Snake" is also offered for $1.00 (Postpaid).

Should you have any further questions, please do not hesitate to write us at: P.O. Box 9216, St. Louis, Missouri 63117. ●

ANNOUNCEMENT

SEARCH FOR GILAS

Several banded gila monsters *(Heloderma suspectum cinctum)* have been illegally collected from a study area in Washington County, Utah. The gilas are important to the Master of Science project of Daniel D. Beck, Utah State University, Logan, Utah. Some of the specimens involved are *marked and numbered by toe-clipping.*

If you have acquired any *toe-clipped* gilas in the past several months or have any information possibly concerning these gilas, please contact:

THE HISTORY OF THE CONCEPT OF VIVIPARITY IN THE ALLIGATOR LIZARD GENUS *Barisia*

Ever since Stebbins' review of gerrhonotine lizards appeared (1958), all members of the genus *Barisia* have generally been thought to be viviparous. (The term "ovoviviparous" has often been applied, indicating egg-retention to birth without formation of a placenta, but Guillette [1981, 1982] has shown that a placenta is present in all viviparous lizards so far as known, and that it is unlikely on physiological grounds that embryos can reach full term in any squamatan without presence of a placenta. Hence live-bearing squamatans are all thought to be in reality euviviparous, having a placenta. Indeed it appears that all viviparity is euviviparity; we thus utilize the former, non-commital term.) Prior to that time it was considered likely that some species or subspecies are oviparous (*e.g.* Tihen, 1949:252), but evidence obtained subsequently has borne out the validity of Stebbins' generalization.

However, the evidence of viviparity in the genus began to accumulate long before Stuart (1948) recorded it in *moreleti*, the earliest date noted by Fitch (1970:111-112) for any member of the genus. The latter author credited Stebbins (1958:18) for the first record of viviparity in *imbricata*, but Bocourt (1879:366) noted its occurrence even earlier.

Gadow (1905:217) made a sweeping statement that all species of *Gerrhonotus sensu lato* (including *Elgaria, Barisia* and *Abronia*) in Mexico are viviparous, but on what grounds is not apparent. Certainly no species of *Elgaria* or *Gerrhonotus sensu stricto* in Mexico is viviparous, hence his generalization cannot be accepted as valid for any species for which viviparity is not otherwise confirmed.

Actually the earliest explicit report of viviparity for any species of *Barisia* is contained in Wiegmann's (1828:382) account describing the first species known of the genus. His statement follows (translated from the German): "In a pregnant female of the same species [*rudicollis*] I found five rather well developed young and two yolk masses in the uteri; it accordingly brings living young into the world, which state perhaps occurs in the other species [of *Gerrhonotus sensu lato* as then known]."

Wagler in 1833 (text for pl. 34, fig. 2) stated that *Gerrhonotus* gives birth to living young, in the account for *lichenigerus* (the only species dealt with in that work), a synonym of *imbricata*. However, no documentation was given for his generalization, which we presume was drawn from Wiegmann's conjecture extrapolating from his discovery of nearly full-term young in a specimen of *rudicollis*.

Wiegmann (1834:34) provided a more detailed account of those young. His comments (translated from Latin) follow, in part: "Opening the venter of one female, I observed the oviducts filled with five young animals and, in addition, two yolk-masses; it is certain that

[this species] is live-bearing, and to me it does not seem unreasonable to speculate the same for the other species [of the genus *Gerrhonotus* as then understood]." The description notes that the fetuses are extremely similar to the adults, with a few differences that are now well known to be characteristic of immature animals, and that their coloration is just the same as in the adults.

Duméril and Bibron (1838:396) also assumed, from Wiegmann, that all species of the genus *(sensu lato)* are viviparous, and they restated (in French) Wiegmann's 1834 description of the uterine young of *rudicollis*.

Almost equally as interesting a comment in Wiegmann (1834) as the description of the young is the only indication in the literature of the habitat of *rudicollis:* "Deppe found this species in oak forests hidden among rocks much like skinks" (translated from Latin, *loc. cit.*). This observation suggests that Tihen's conjecture (1949:240) that the species is arboreal, based upon pattern and long limbs, may not be justified. However, the species would have to compete with *imbricata* if it is terrestrial, with *Abronia deppei* (Sanchez-Herrera and Lopez-Forment, 1981) if it is arboreal, for both occur in the same general area (western part of the state of Mexico) and are very likely sympatric. Competition in both habitats may well have led *rudicollis* to marginal existence; its rarity in collections may well reflect a rarity in nature and not the vagaries of collecting effort and skill. Nevertheless, *Abronia deppei* is equally rare in collections in that area, known only by the material reported *(op. cit.)* from the Sierra de Temascaltepec one km SSW Valle de Bravo, Mexico (state), although ample material is known from central Guerrero in the Omiltemi area, where much more collecting has been done. Sympatry does not necessarily lead to competitive exclusion, however, as indicated by the report of Bogert and Porter (1967:19) of three species of gerrhonotine lizards sympatric at Tejocotes, Oaxaca - one arboreal *(Abronia mixteca)*, the other two terrestrial *(Barisia gadovi levigata, Gerrhonotus l. liocephalus)*.

FURTHER NOTES ON PARASITES OF ZAMBIAN REPTILES

Of late, there has been increased interest among biologists and especially zoo keepers in parasites of African reptiles because of their patho-physiological importance in free ranging and captive animals and their effect on host behavior.

Except for studies by Mettrick (1950), Colbo (1973) and Simbotwe (1979), literature on African reptile parasites is scanty.

During the monthly examination of reproductive tracts and gut contents of reptiles from Dambwa Forest Reserve and Lochinvar National Park, endoparasites were collected. General accounts of collecting localities were given by Douthwaite and Van Lavieren (1977), Sheppe and Osborne (1971), and Simbotwe (1979). Simbotwe (1979) emphasized methods of parasite preparation, parasite life histories and host-parasite associations. This paper

Mabuya varia (Peters)	*Abbreviata* spp.	nematoda	stomach	Lochinvar National Park
	Thelandros spp.	nematoda	stomach	Lochinvar National Park
Lygodactylus chobiensis FitzSimmons	*Pharyngodon* spp.	nematoda	stomach	Lochinvar National Park

presents a list of ten metazoan parasites and their host animals with comments on pathonogenic ascarids and cestodes of snakes, eight of which were new records for Zambia (Table 1). The recovery of *Spirura* spp. from *Mabuya striata* which apparently is not a normal parasite of reptiles (Gibbons pers. comm.) is interesting. It is possibly from the animal eaten by the host. A large number of ascarids, *Polydelphis anoura*, were recovered from a 3.5 m African rock python, *Python sebae*. These ascarids, including the cestode *Bothridium pithonis*, were found in the stomach walls of the host apparently causing severe ulceration and tumours. The infected host exhibited aggressive behavior which is atypical of captive pythons. I attributed this behavior to the possible discomfort experienced by the host as a result of stomach ulcers and tumours.

Parasites were deposited in the Commonwealth Institute of Helminthology and the Livingstone Museum under catalogue numbers NMZL 1 to 27.

ACKNOWLEDGMENTS

Thanks to Mr. A. S. Muyundu for excellent assistance in the field. I also wish to thank Dr. R. Muller, Director of the Commonwealth Institute of Helminthology and Dr. Lynda Gibbons who identified the parasites. My colleague J. D. Miller constructively criticized the earlier drafts. Research was supported in full by the National Museums Board grant to the Department of Natural History, Herpetology Division.

A NEW SIZE RECORD FOR THE SALTWATER CROCODILE *(Crocodylus porosus)*

On 11 October 1979 a very large male saltwater crocodile *(C. porosus)* drowned in a fishing net at Obo, approximately 320 km above the mouth of the Fly River in the Western Province of Papua New Guinea (07°37'S, 141°18'E). The carcass had already been slaughtered and the meat divided amongst the local Zimikani villagers, but the complete head, commercial skin (cut from the posterior edge of the mandibular symphasis to the 24th row of caudal scutes, and minus the four dorsal scute rows), and the distal tail (caudal scute rows 24-38) were still at the site 14 hr after the animal drowned.

Figure 1. The commercial skin of a 620 cm saltwater crocodile *Crocodylus porosus* killed on 11 October 1979 near Obo, 320 km up the Fly River in Papua New Guinea. (Photo by Romulus Whitaker.)

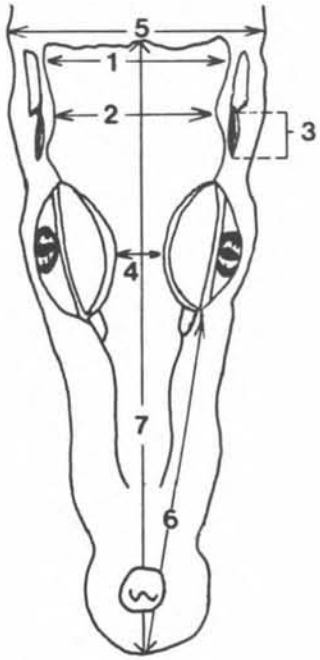

Figure 2. *C. novaeguineae* head showing measurements. 1) Width of cranial platform (HPP). 2) Cranial platform mid-point width (HMP). 3) Ear slit length (EL). 4) Interocular width (HIO). 5) Maximum head width (HMW). 6) Snout-eye length (HSE). 7) Total head length (HTL).

By laying out but not stretching the unsalted skin (Figure 1), placing the head and tail tip in position, and measuring between pegs placed at each end, the total length recorded was 620.2 ± 1 cm (Table 1). Fifteen other measurements were also recorded (Figure 2; Table 1). The skull, teeth and skin are currently at the Wildlife Office, Konedobu, Papua New Guinea.

Although quantitative data are unavailable, crocodile skins generally shrink to some degree after removal from the animal. And since the Obo *C. porosus* skin had dehydrated in the sun at 32-38° C for 14 hr before it was measured, the skin morphometrics reported in Table 1 probably underestimate its live dimensions.

The crocodile appeared in excellent health, and other than one old scar (anterior to the right femur), the skin was unblemished. Teeth were in good condition and had replacement tooth buds in various stages of development. The villagers stated that a complete rusa deer *(Cervus timorensis)* had been removed from the stomach.

George Craig (personal communication 1980), who hunted the Obo area in the 1960's, often saw and unsuccessfully tried to catch a large crocodile there, which the local people believe to be the same animal.

Predicting TL from SVL using formulae in Webb and Messel (1978) indicated 621.9 ± 2.3 cm, a value in close agreement with our TL estimates. Predicted live body weight (BWT) = 1019 ± 104 kg. Predicting TL from a combination of morphometric data (their formula 137) indicated a low value (513 cm), which is consistent with the wide variation of head proportions in large *C. porosus*.

The data in Table 1 agree with Webb and Messel (1978), in that Bellairs' (1969) ratio of head length to total length of 1:7.5, and Wermuth's (1964) ratio of 1:7.48 do not apply to large *C. porosus*. They also support the conclusion of Webb and Messel (1978), Schmidt (1944) and Greer (1974), that the skulls described by Boulenger (1889) and Barbour (1924) are not from crocodiles of 8.8 m and 10.1 m respectively. The HTL ratios of 1:8.57 and 1:9.23 for the Obo and Mary River *C. porosus* (Webb and Messel 1978) respectively suggest that crocodiles approaching the maximum TL for the species have HTLs proportionately shorter than those of the rest of the population. Predicting TL from HTL using formulae derived from *C. porosus* up to 4.3 m gave an estimate of 5.2 m, a substantial underestimate. It is interesting to note that Webb and Messel's equation for predicting TL from SVL for male *C. porosus* (up to 207 cm SVL) gives a realistic prediction of the Obo crocodile TL.

The Obo crocodile is believed to be the largest saltwater crocodile yet measured for which recorded morphometric data together with skull and skin are available. The next largest is the 615 cm specimen from Mary River, Australia, discussed by Webb and Messel (1978), for which only the skull is preserved. The good condition of the Obo crocodile suggests that TL's in excess of 620 cm may be possible for *C. porosus*.

I am indebted to O. Saiga of Kavianangа Village for holding the remains of this crocodile until my arrival, to E. Balson, A. Graham, P. Hall, G. Webb and R. Whitaker for critically reading this manuscript, and to J. Lang for his advice on crocodilian morphology.

Table 1. Morphometric data for the large *C. porosus* drowned near Obo on the Fly River, Papua New Guinea. Measurements follow the method of Webb and Messel (1978) and are in centimeters and kilograms.

Measurements	Fresh	Dried
Head platform width (HPP)	22.3	22.0
Head platform mid-point width (HMP)	20.5	20.4
Ear slit length (EL)	12.9	—
Interocular width (HIO)	8.5	8.1
Head maximum width (HMW)	45.1	45.0
Snout-eye length (HSE)	50.6	50.5
Head total length (HTL)	72.0	70.0
Weight of head with teeth	49.2	26.0
Snout-vent length (SVL)	304.0	
Total length (TL)	620.2	
Neck girth (NG)	150.6	
Commercial belly-width (girth at the third most anterior row of dorsal scutes minus the width of the 4 dorsal scute rows)	151.2	
Vent length	8.5	
Width of the largest nuchal scute	4.8	
Largest tooth		
length	13.9	
diameter	3.1	
weight	0.09

OBSERVATIONS ON THE LAMINAL SPURS OF *Gopherus polyphemus*

Allen and Neill (1957) made mention of the juvenile gopher tortoise having laminal spurs growing on the posterolateral margin of each humeral lamina.

In March 1979 a juvenile gopher tortoise was collected south of Savannah, Georgia. I decided to keep this tortoise in a twenty gallon aquarium to observe it. I placed several inches of clean white sand, number 1 grit, as a medium on the bottom. Also included was a shallow water dish 5/8 inches deep and 4 inches in diameter. A hide box open on one end and numerous pieces of log and cork bark, and other materials were scattered throughout the cage.

The juvenile tortoise was estimated to be six months old. The umbilical area was covered with a wrinkled plate and was very soft and pliable. The hind legs were very thin and delicate in structure, almost too delicate to support the weight of the turtle. The tortoise dug constantly in the sand, perhaps trying to construct a tunnel. It climbed over all the obstacles in the tank and was extremely active most of the day. it was often observed soaking in its water dish. Larger obstacles in the tank were insurmountable in a single try and it would pause to rest several times during the attempt. It would use its forelegs to pull itself up an incline and then place its plastron flat against the substrate anchoring one of its sharp spurs. It thus appeared to hold on so that it would not slide backwards and lose ground.

Baby gopher tortoises dig their own burrows shortly after hatching, usually beneath a clump of wiregrass. It is probable that the juvenile tortoises also use existing tunnels created by mice and other rodents. The burrows that they dig are thirty to thirty-six inches deep.

From my personal observations of a number of specimens, I believe that these spurs are beneficial to the juveniles climbing out of steep burrows. They anchor the spurs in the clay and sand to keep the tortoise from sliding backward as it climbs up the steep ramp of the burrow.

I have obtained other juveniles since the first one was caught and have had the opportunity at the Savannah Science Museum in Savannah, Georgia to check nearly fifty live specimens of assorted sizes for spurs. Tortoises four-to-five inches in length usually had a blunt worn spur, and the adults had no indication that a spur had ever existed. As the tortoises get older and larger the spurs appear to wear down, probably by the abrasiveness of the sand in their natural habitat. An occasional midsize specimen would have a sharp well pronounced spur (Table 1).

A hatchling indigo snake *(Drymarchon couperi)* was kept in the same tank with several juvenile gopher tortoises. On several occasions when dead mice were placed in the tank for the indigo snake to eat, the tortoises were observed pulling on the fur and trying to bite into the mouse. When pink mice were fed to the snake, the tortoises were observed carrying the mice about the cage in their mouths.

Other observations on juvenile gopher tortoises have been reported by Allen and Neal (1957a) and Arata (1958).

ACKNOWLEDGMENTS

I would like to thank Gerald K. Williamson, Director of the Savannah Science Museum and Charles W. Seyle Jr., Research Associate at the Savannah Science Museum for their assistance in the field and allowing me to examine their specimens and to use their notes.

MEETINGS

The editor would like to encourage the submission of any and all information concerning *special* meetings related to herpetology, for publication in **HR.** Publication of the existence of a meeting, along with a contact person's name and address, is a service to the herpetological community even if a tentative program has not yet been established. Please note that the deadline dates for the March, June, September and December issues of **HR** are the first days of the previous months. Communications from non-U.S. correspondents should take into account the expected postal delays. Announcements from regional herpetological societies should be directed to Janice Perry, the SSAR Regional Society Liaison; all others should be sent to the editor. ●

AMPHIBIAN AND REPTILE HUSBANDRY AND PROPAGATION CONFERENCE

The Northern California Herpetological Society is sponsoring a conference on 15 October 1983 dealing with the propagation and husbandry of amphibians and reptiles. The conference will be held at the University of California, Davis. The keynote speakers will be Dr. Fredric Frye and Dr. Murray Fowler, with other invited speakers consisting of a cross section of academic, institutional, and private herpetologists. The proceedings will be published. Further information can be obtained by writing: the Northern California Herpetological Society, 706 Arnold Street, Davis, California 95616. ●

ANNUAL MEETING OF THE AMERICAN ASSOCIATION OF ZOO VETERINARIANS

The annual meeting of the American Association of Zoo Veterinarians will be held from 23-27 October 1983 at the Holiday Inn International, Tampa, Florida. For further information contact: Dr. M.S. Silberman, Executive Secretary, American Association of Zoo Veterinarians, PO Drawer TT, Emory University, Atlanta, GA 30322. ●

EASTERN SEABOARD HERPETOLOGICAL LEAGUE MEETING

The Eleventh Spring Meeting of the Eastern Seaboard Herpetological League (ESHL) will be held on Saturday, 15 October 1983, at the Philadelphia Zoo. The meeting will consist of a series of presentations on many aspects of herpetology. Dr. Peter C.H. Pritchard will be the keynote speaker. Any individual interested in herpetology is invited to attend this one-day meeting. There is no admission or registration fee. For further information contact Malvin Skaroff, 1555 Pratt Street, Philadelphia, PA 19124. ●

SEVENTH REPTILE SYMPOSIUM ON CAPTIVE PROPAGATION AND HUSBANDRY

The Seventh Reptile Symposium on Captive Propagation and Husbandry will be held on 3-6 August 1983 in Dallas, Texas, hosted by the Dallas Zoo. The meeting will take place at the Quality Inn one mile northwest of downtown Dallas. In addition to contributed papers, there will be special events and tours of the herpetological collections at the Dallas Zoo and the Fort Worth Zoo. For program information contact Dr. Peter J. Tolson, Curator of Reptiles, Toledo Zoological Society, 2700 Broadway, Toledo, OH 43609, (419)-385-5721. For preregistration information contact Richard A. Hahn, Zoological Consortium, Inc., 13019 Catoctin Furnace Road, Thurmont, MD 21788, (301)-271-7488. ●

REPRODUCTION IN A FAN THROATED LIZARD *Sitana ponticeriana*

This note provides the first information on the eggs and hatchlings of the fan throated lizard, an agamid ground-dwelling lizard *Sitana ponticeriana* Cuvier. Observations were made on ten different occasions on the grounds of Kapilathirtham field area, Tirupati (13°8'N and 79°4'E) in Andhra Pradesh. Morphometrics of the eggs were taken at 1, 10, 20 and 30 days and hatchlings were measured.

In this species, eggs are laid only during the rainy season (July to October). The specimen under observation laid 8 eggs in a hole measuring 60.5 mm vertically and 64.2 mm diagonally with a diameter of 22.5 mm (Fig. 1). She laid all the eggs (8) in 5 min and 45 secs, the interval between the eggs being 40-45 secs. The time taken for digging the hole was 48 min and closing the same after laying the eggs was 34 min 45 secs.

Figure 1. Longitudinal section of the hole in which the eggs were laid by *Sitana ponticeriana*.

The eggs are small and ellipsoidal with a soft shell. The clutch size varied from 8 to 13. However it is interesting to record that one animal of *Sitana ponticeriana* laid 36 eggs in three different clutches (11, 12 and 13) in a period of 41 days. Mortality was 89% (calculated on the basis of 112 eggs laid in 10 clutches by 8 different animals).

The mean sizes of the eggs on the 1st and 30th days were 5.94 X 8.75 and 9.3 X 12.1 (mm) respectively. The weight of the eggs laid on the 1st day increased from 0.1 to 0.25 gm up to the 30th day (Table 1). Most of the increases in the egg sizes occurred during the first half of the incubation period of 40-45 days. One egg was broken on day 20 and two were eaten by ants by day 30.

Table 1. Mean dimensions (length X width) in mm of the eggs of *Sitana ponticeriana* during incubation.

1st day	10th day	20th day	30th day
8.75 X 5.94	10.38 X 7.7	11.0 X 8.3	12.1 X 9.3

Table 2. Weights and sizes of fan-throated lizards, *Sitana ponticeriana* immediately after hatching (1st day).

N	Sex	Weight (g)	Total length (mm)	Snout-vent length (mm)	Tail length (mm)
1.	Female	0.177	49.10	16.55	32.55
2.	Female	0.166	49.00	16.50	32.50
3.	Male	0.175	47.50	17.25	30.25
4.	Male	0.170	48.50	17.00	31.50
5.	Male	0.178	49.00	17.50	31.50
	MEAN:	0.173	48.62	16.96	31.66

The mean weight of the young ones irrespective of sex immediately after hatching was 0.173 gm and snout-vent and total lengths were 16.96 mm and 48.72 mm respectively (Table 2).

Thanks are due to Dr. B. S. Rajabai, Department of Zoology, Sri Venkateswara University, Tirupathi, A.P., India for guidance; to the Secretary, University Grants Commission, New Delhi, for financial support and to Dr. Kraig Adler, Section of Neurobiology and Behavior, Cornell University, Ithaca, New York for reading the manuscript and offering helpful suggestions.

The Association of Systematics Collections

is expanding its activities to more directly serve the needs of individual systematists. This move is a logical extension of the ASC's role since the researcher and the institutions which house systematic collections are not independent entities. Rather, each is dependent upon the other to perform its function, and together they comprise the systematics community. In addition, such a unification is the only basis to affect national policy with regard to systematic biology.

To achieve these goals, the ASC is offering individual subscriptions with many of the benefits available only to institutional members in the past. Benefits include:

Subscription to the ASC Newsletter

The *Newsletter* is a bimonthly publication with articles of interest to systematists. Recent issues have included such topics as: collection management, publication reviews, positions available in the community, legal issues, grant information and symposium announcements.

Publication Discounts

Newsletter subscribers receive a 20% discount on all ASC publications. Recent publications include: *Pest Control in Museums, Museum Collections and Computers*, and soon to be published, *Sources of Federal Funding for Biological Research* and *Controlled Wildlife—a three volume guide to U.S. wildlife laws and permitting procedures.* Discounts on publications could more than off-set your annual subscription price.

Annual Meetings

Individuals will also be welcome to attend annual ASC meetings. At these meetings individuals meet to exchange ideas and discuss topics of mutual interest and benefit. Symposia at recent meetings included: a review of the Biological Research Resources Program of the National Science Foundation, Ethics and Responsibilities of Curators, Directors and Trustees in Collection Management, and Biogeography of the Tropical Pacific.

Representation

The ASC is taking steps to provide resident representation in Washington, D.C. to make policies adopted by our constituency known to Federal agencies, legislative committees, and funding programs. Our goal is representation from our constituency on every policy oriented body associated with funding programs servicing systematic biology. Your ASC subscription offers you the opportunity to participate in the decisions guiding this program.

To subscribe, fill out the form below and return it to the ASC office. The form provides several subscription categories. Though the benefits are no greater in the higher categories, your contribution will be greatly appreciated. We hope that you will join with us in solidly establishing a unified voice for systematics. If you already are a subscriber, please encourage at least one colleague to join us.

TECHNIQUES

VENOMOUS SNAKE IMMOBILIZATION: A NEW TECHNIQUE

Immobilizing venomous snakes for purposes of determining sex or administering drugs often presents a difficult problem and a variety of solutions have been suggested. Anesthesia (Brazenor and Kaye, 1953; Karlstrom and Cook, 1955; Betz, 1962; Hackenbrock and Finster, 1963 and Wang, Kubie and Halpern, 1977) and various mechanical restraints have been used for this purpose. Murphy (1971) suggested the use of clear plastic tubes for both manipulative and surgical procedures. Similar methods are described by Johansen (1959) and Sutherland and Hampton (1961) who employed the use of flexible polyvinyl tubes. McDonald (1964) taped snakes directly to wooden dowels slightly larger than the diameter of the snake. Luck and Keeler (1929) used a wooden trough in a similar fashion while Ward and Howell (1978) used a board with padded velcro straps to pull the snake taut against the surface.

Each of these methods is certainly an effective method of snake immobilization, but when put into practice involves a great deal of manipulation and hands-on contact which, when the snake is venomous, subjects the handler to considerable risk. Here we suggest a novel method which involves much less manipulation and yet has proven effective in both determining sex (by probing; see Laszlo, 1973) and drug administration.

A plastic bucket with a lid was notched on the upper lip to a depth of 4 centimeters so as to accommodate medium-sized snakes (Fig. 1A). A snake is then placed, using a snake-handling hook, over the lip of the pail so its midbody lies in the notch and its head is within the bucket (Fig. 1B). Immediately subsequent to this placement, the lid (to which a handle has been attached) is placed onto the bucket (Fig. 1C, D). Simultaneously, the tail region of the animal is grasped by hand to prevent its withdrawal into the bucket (Fig. 1E). This allows the handler access to about the posterior one-half of the animal and sexing or drug injections can be easily accomplished (Fig. 1F).

The lock rings on the bucket covers were not removed, but during the immobilization process the cover was not pressed shut to the point where the tabs were engaged. In actuality this takes a great deal of pressure. We do not recommend that these tabs be used to lock the cover due to the difficulty in opening the lid from a locked position. We do recommend, however, if further security is desired, that a length of cord be tied to the pail handle base on one side, passed through the lid handle and secured to the opposite handle base, especially for manipulations of longer duration.

We feel this method of restraining snakes is as simple as it is effective. Different sized buckets with notches cut accordingly have been used to accommodate snakes of different sizes. We have encountered minimal resistance by the snake to grasping the tail, and because of this feel that the use of this method subjects the snake to minimal traumatization. Additionally, this method is not only relatively safe from the handler's standpoint, but can be used rapidly, and large numbers of animals can be temporarily restrained and released in a very short time period. We feel this method of venomous snake immobilization to be the most satisfactory for the purposes described above.

A RAPID PLOTTING AND ANALYSIS PROGRAM FOR NUMERICAL DATA

Hubbs and Hubbs (1953) proposed an improved graphical analysis technique for the comparison of numerical data in series of samples. This technique employs the range, mean, standard deviation, and two standard errors to each side of the mean of each sample for comparison. The Hubbs and Hubbs graphs have proven to be a useful tool for making visual assessments of statistical differences between several samples. This technique has gained popularity in recent years as a tool for comparing data from studies of critical thermal maxima (Hutchison, 1961; Spotila, 1972; Hassan and Spotila, 1975), temperature selection (Feder and Pough, 1975), metabolic rates (Holzman and McManus, 1973), and thermal tolerance (Heath, 1963; Pough and Wilson, 1970).

Andreasen (1976) described a computer program to draw Hubbs and Hubbs graphs using an automatic plotting device (the CalComp plotter). The program user must supply the range, mean, standard deviation, and standard error for each group. Although the program provides the user with a high quality product, much time must be spent computing the sample statistics for input.

This paper describes a FORTRAN program that provides a line printer plot of Hubbs and Hubbs graphs using raw data furnished by the user. The program also supplies the user with several sample statistics and analyses. The plot is only intended to allow rapid visual assessment of differences between group means. The determination of significant differences between means requires more rigorous multiple comparison procedures.

This program was written to plot and analyze a maximum of 50 data points for up to 50 separate treatment groups. These limits were chosen because they are large enough to handle most collected data and small enough to remain within the bounds set for rapid execution at most central computer facilities. An increase in storage requirements, to accommodate larger data sets, can be easily accomplished.

The program was written in standard FORTRAN language for the WATFIV compiler. Statistical procedures follow the methods outlined by Steel and Torrie (1960) and Sokal and Rohlf (1969). Each section of the program was written as a separate subroutine and tested individually. The entire program was then tested against programs in the statistical library of University Computing Services at The University of Oklahoma. All tests were conducted on an IBM 370 Model 158.

The plotting portion of the program was designed to accept character strings to define labels on the ordinate and abscissa. One of five optional ranges is selected for scaling the ordinate. Scaling on the ordinate varies from 0.05 unit/division to 1.0 unit/division depending on the range selected. The abscissa has a fixed scale and labels are printed for each group. The program was designed to accept numerical values between -999.999 and +999.999.

Diagnostic messages were built into the program to assist the user in the event that data are omitted or the data deck is improperly stacked. The WATFIV compiler also provides extensive diagnostics for the user.

Figure 1 is a typical printer plot of critical thermal maxima (CTM) measured under six different treatments in the mudpuppy, *Necturus maculosus*. A range of ten units, beginning at 28° C, was supplied by the user to scale and label the ordinate. The data are from Erskine and Hutchison (1981).

The exact positioning of range, mean, and two standard errors to each side of the mean are subject to some round-off error. Round-off error is reduced if the range over which the data are plotted is decreased. The effect of reducing the range is to increase the resolution of the plot.

The output of the program also includes a table of input data as a permanent record, sample statistics for each group, a single classification analysis of variance between groups (Model I or Model II ANOVA), a test for homogeneity of variance, and the maximum variance ratio.

The strength of the program is that it offers a convenient and inexpensive printer plot of Hubbs and Hubbs graphs for quick reference. The program is sufficiently flexible to allow analysis of data from a wide range of studies, and since all of the analyses are performed on a single data set the data need not be resubmitted for each statistical test. Complete analysis saves time and circumvents the difficulty of incompatible data formats between common library packages. Finally, the knowledgeable user can improve upon the efficiency of the program by reducing the storage requirements when small data sets are analyzed.

A program listing, source deck, test data with output, instructions for stacking the data decks, and a detailed explanation for reducing storage requirements are available from the author.

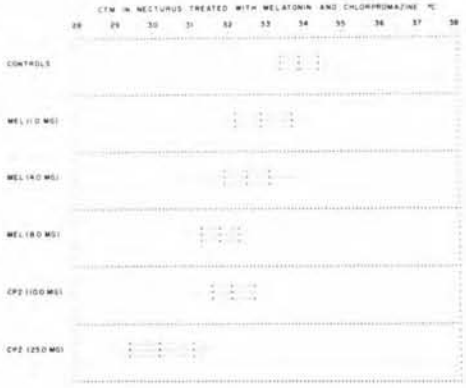

Figure 1. A typical printer plot of the Hubbs and Hubbs graph of critical thermal maxima (CTM) measured for six different treatments in *Necturus maculosus*. Two standard errors to each side of the mean are represented by the rectangular box. The mean for each group is defined by (X) and the range is the dashed (---) line through the center of each open box. Figure labelling was redrawn because printer alphanumerics would be illegible after reduction.

ACKNOWLEDGMENTS

I wish to express my appreciation to Victor H. Hutchison (Department of Zoology) and Richard V. Andree (Department of Mathematics), University of Oklahoma, for reading the manuscript and offering many helpful suggestions.

AN ALTERNATIVE METHOD TO SAND-PACKED INCUBATION OF SEA TURTLE EGGS

Current practice for the artificial incubation of sea turtle eggs, widely used in conservation practices, employs sand-packed styrofoam boxes which can be transported to hatcheries or locations other than the turtles' nesting beach. Temperature and oxygen levels in sand-packed styrofoam boxes have been previously summarized with an expected temperature rise during incubation of up to 5° C, depending upon hatchability of the clutch (Wood and Wood, 1979). Oxygen levels in both artificially and naturally incubated nests generally decrease from 21% to 16-12% (Ackerman, 1975). The effect of artificial incubation of eggs, particularly the temperature effects on sex ratio, has been reviewed (Mrosovsky and Yntema, 1980).

At a sea turtle farm in the Cayman Islands, over 40,000 eggs from a captive breeding population of *Chelonia mydas* are artificially incubated annually. Hatchery conditions and incubation techniques have been previously described (Wood and Wood, 1979). Briefly, all eggs are collected as laid, transferred to a hatchery maintained at 27.5° C, and incubated in sand-packed styrofoam boxes. The quantity of eggs handled and the desire to maintain a high degree of cleanliness have indicated the need for an alternative to sand for packing the eggs.

During the 1979 season, nine clutches were divided and incubated in sand or foam. For foam-packed eggs, a layer of polyethylene foam 3.8 cm thick was placed inside the styrofoam box (36 x 21 x 23 cm, perforated with an icepick approximately every four cm^2), the eggs were layered directly on the foam (28-32 eggs, maximum three layers), another layer of foam was placed snugly over the eggs, and then the perforated lid of the styrofoam box was put on. Each box contained 56-97 eggs. Percentages of undeveloped eggs, developing eggs not hatching, and hatched eggs for sand-packed boxes were 20.2, 31.3, and 48.4%, respectively. Percentages for foam-packed boxes were 15.2, 27.2, and 57.7%, respectively. Following this trial, the remaining 4,400 eggs collected in 1979 were incubated in foam-packed boxes with a resulting hatch of 29.8% compared to 26.2% for the other 42,000 eggs packed in sand during the season. Temperature levels in the foam-packed boxes were similar to those in sand-packed boxes. Oxygen levels tended to decrease less in foam-packed boxes than in the sand-packed boxes. In sand-packed boxes, oxygen levels decrease from 21% to as low as 14%; in foam-packed boxes, the minimum level recorded was 17%. Oxygen levels in the nests begin to decrease and temperature levels begin to increase on approximately day 30 of incubation. Both oxygen and temperature levels are dependent upon the number of developing eggs in the nests. The sex ratio of 800 hatchlings which died during a period of 12 months after hatching was 1.0:1.3 (females:males).

Foam-packed boxes are currently used for the incubation of all eggs collected at Cayman Turtle Farm's breeding facilities. The ease with which foam can be handled as compared to sand simplifies the large scale handling of sea turtle eggs with no apparent adverse effects when incubated at an ambient temperature of 27.5° C.

IDENTIFICATION OF SEX OF SMALL SNAKES IN THE FIELD

Identification of sex of living newborn or newly hatched snakes often presents a problem in the field. Probing for the inverted hemipenes of the male (Fitch, 1960; Platt, 1969) is difficult, or dangerous to the snake, and although sex can in theory be determined from the shape of the tail base (Martof, 1954), as in adults, most herpetologists would probably not be able to sex neonates using this criterion alone. In many species, the tail length to total length (body plus tail) ratio is sexually dimorphic (Martof, 1954; Fitch, 1960; Jackson and Franz, 1981), but overlap between the sexes often negates the usefulness of this as an index (Martof, 1954). Martof (1954) indicates that male and female newborn *Thamnophis* can be distinguished by the yellow coloration of the ventral surface of the base of the tail in females, due to the large cloacal glands being visible through the skin. Martof's identifications using this method were verified by a few dissections but he also mentioned that some could not be sexed externally and had to be dissected. Dissection is a sure method for sexing small snakes (Gregory, 1977; Semlitsch *et al.*, 1981), but is obviously not very useful in mark-recapture population studies. My objectives here are to describe and assess a simple method for sexing very small snakes in the field. This technique is not original, but I have not seen previous mention of it in the literature. A likely similar technique ("post-cloacal hemipenial distention") was mentioned by Freedman and Catling (1978), but they did not give details or data assessing its effectiveness.

The method described here relies on the anatomy associated with the hemipenes of male snakes. The two hemipenes are inverted into the base of the tail when not in use, allowing sexing by probing in larger snakes. In small snakes (*e.g.* neonate *Thamnophis*), the hemipenes can be made to evert in response to firm pressure by the thumb at the ventral surface of the base of the tail just posterior to the position of the inverted hemipenes. This does not seem to harm the snakes in any way. With increasingly larger *Thamnophis* specimens (>300 mm snout-vent length, SVL) known to be males, the method works increasingly less often, but even when it does, considerable pressure may be required to make the hemipenes pop out. However, when the hemipenes pop out in small snakes, they do so quickly and easily, suggesting that presence or absence of this response might be a useful means of sexual identification in the field.

I used this technique to sex 71 newborn young of 9 female garter snakes (8 *Thamnophis ordinoides* and 1 *T. sirtalis*). The SVL of the young snakes ranged from 115-155 mm and 170-180 mm for *T. ordinoides* and *T. sirtalis* respectively. The apparent sex ratio of these snakes was 35 ♂♂:36 ♀♀. The young were then killed by freezing and preserved for later examination. Those identified as males were taken to be positively identified, but those labelled as females could have been either females or males whose hemipenes failed to evert. To identify small snakes to sex by dissection I looked for the presence or absence of the two large hemipenial retractor muscles which run lengthwise on the ventral surface of the tail of the male (Bellairs, 1969). Females lack these muscles; the cloacal glands are the only large structures visible upon dissecting the base of the female's tail. Two snakes identified as females were lost, leaving a total sample of 34 "females." Of these 34, 3 (all *T. ordinoides*) were misclassified males, so that after adding these to the 35 known males, only 3/38 = .079 of all males were misclassified. For the total sample of 69 snakes, only 3/69 = .043 were misclassified. Considering the ease with which the method is used, and the lack of equipment needed, this seems a suitable method to use for live sexing of neonates, or other small snakes, in the field.

It should be noted, however, that this technique may not be equally suitable for all kinds of snakes. In male rattlesnakes *(Crotalus viridis)*, the hemipenes usually evert in both neonates and large adults when the tail is pulled slightly such as when measuring SVL. I dissected 11 neonate *C. viridis* independently sexed by another researcher using the hemipenis-popping method and confirmed the identification for each (6 females, 5 males). On the other hand, when I attempted to sex 8 newly hatched fox snakes *(Elaphe vulpina)* using this method, I found that great pressure was required to make the hemipenes pop out and obtained two different sex ratios on consecutive attempts (1 male the first time and 2 the next). I did not confirm the sex ratio by dissection because the snakes were needed alive for other purposes but I would accept such sex ratio data for this species (and possibly other constrictors) with more caution than data for the other species mentioned. Perhaps preliminary testing is

desirable before the technique is applied to a particular species.

ACKNOWLEDGMENTS

I thank Malcolm Macartney for supplying me with specimens of newborn rattlesnakes.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

TWO GENERATIONS OF CAPTIVE-HATCHED LEOPARD TORTOISES, *Geochelone pardalis babcocki*

On March 1981 a hatching leopard tortoise, *Geochelone pardalis babcocki*, was discovered at approximately 1545 in an incubator which had last been checked on 18 March 1981. This was the first hatchling from a clutch of eggs laid on 17 October 1980.

The female parent had been maintained with a sibling male. Both parents were captive-hatched between 1 June and 21 July 1973. These two tortoises were not in contact with other tortoises between 18 May 1978 and 17 October 1981. Prior to 18 May 1978 they were maintained with immature siblings. On 18 October 1981 an unrelated captive-hatched male was added to the pair. The hatchling of 20 March 1981 and the eight subsequent hatchlings of 1981 and 1982 were the result of breeding of these two captive-hatched parents.

Bowler (1975) described a Galapagos tortoise *(Geochelone elephantopus)* which hatched at the Philadelphia Zoo. Its mother was hatched in captivity, but its father was wild caught. Kirsche (1979) mentioned captive-hatched *Testudo h. hermanni* laying their first clutches between 11 and 14 years of age, but did not mention hatchlings from these clutches. This paper represents the first published record of second generation captive-hatched tortoises whose parents were both captive-hatched.

Materials and Methods

The F1 tortoises were housed in two different facilities. The outdoor pen was 5.5 X 3 m with walls of wire and wood 1 meter high. A wooden shelter was provided. Vegetation growing in the pen included grasses, dandelions, clover and unidentified weeds. A stainless steel water container 60 X 45 X 6.4 cm deep was provided. The water was changed at least daily as the tortoises tended to walk through it, soak in it, and drink from it. The outdoor pen was utilized from June to September, and occasionally in April, May and October. The tortoises were kept outside continually as long as the daytime temperatures remained above 21° C and nighttime temperatures remained above 10° C. By gradually increasing the amount of time the tortoises were left outdoors in the evening they were acclimated to the cooler night temperatures in June. After 1-2 weeks they were left outdoors overnight. If rain persisted for two or more days the tortoises were usually brought in overnight.

From 18 May 1978 to 17 October 1981 the indoor facility consisted of a pen 1.5 X 9 X 0.5 m high with a substrate of wood shavings. The pen contained a box of soil for oviposition. The female nested in this container on 3 December 1980.

The pen had a 250 watt infra-red heat lamp at one end and a four foot (40 watt) Vita-lite® fluorescent tube (Durotest Co.) in a fixture along one side. Both the heat lamp and the Vita-lite® were suspended approximately 46 cm over the wood shavings. The lights were on a 12 h day/night cycle, from 1000 until 2200, regulated by a timer. The pen also received additional early morning light.

Daytime temperatures ranged from 21° C to a maximum of 40° C under the heatlamp. At night the temperature dropped to a minimum of 15° C. The tortoises thermoregulated by moving to different locations in the pen and usually basked under the heatlamp immediately after it came on and after feeding.

On 17 October 1981 a new indoor pen was utilized. It was constructed of plywood 1.2 X 2.4 X 1.2 m high. Wood shavings were used as the substrate and a 250 watt heatlamp was used. The single fluorescent fixture was replaced with a four foot fixture containing two Vita-lite® bulbs. Temperature ranges remained the same as in the pen used previously.

Diet consisted strictly of plant material provided at least 3-4 times per week. No animal protein was fed to either wild-caught parents or their offspring. Their staple diet consisted of lettuce (iceberg, romaine, bib), cucumbers, bananas, tomatoes, green beans, and apples. This was supplemented with a mixture of two parts bonemeal and one part vitamin/mineral powder (Vionate® for Pets Vitamin/Mineral Supplement, E. R. Squibb & Sons, Inc. or Pervinal Nutritional Supplement®, St. Aubrey, Division of 8 in 1 Pet Products, Inc.). The staple diet was varied with dandelions, carrots, watermelons, spinach, squash, berries and other fruits and vegetables as available. All food was washed thoroughly. When the tortoises were outdoors they were fed daily, in addition to grazing on vegetation in the pen. Clean water was always available.

Eggs were placed in a dry air incubator (Brower Manufacturing Company, Quincy, Illinois; catalogue number 846) soon after laying. The clutch laid 31 August 1980 was

placed in the incubator two days after laying. All eggs were marked with the date and a number with a black felt marker in 1980 and with a pencil in subsequent years. Eggs were incubated at a constant temperature of 30° C except for two days when the temperature fell to 25.5° C. Humidity was maintained by filling a 22 cm diameter glass pie plate, containing a sponge, with water. Eggs were sprayed at least twice a week with water from a spray bottle kept inside the incubator.

Table 1. Eggs Laid by F1 Leopard Tortoise *(Geochelone pardalis babcocki)*

Date Laid	# Eggs	# Hatchlings	Date Hatched	Incubation Period	Remarks

			9 Mar 1982	148 days	
24 Aug 1982	6				Eggs incubating
28 Sept 1982	9				Eggs incubating

Observations and Discussion

The parents of the second generation tortoises hatched between 1 June and 21 July 1973 from a clutch of eggs laid 30 December 1972 by a wild-caught female from Kenya. The eggs were the result of a series of matings involving a group of one male and three female wild-caught tortoises maintained together since spring 1971. The male was from Botswana and had been in captivity in California approximately 10 years when he was obtained in 1971. He produced no offspring in California. The females were obtained from a reptile dealer in 1971.

The F1 male first exhibited sexual behavior on 30 July 1977 consisting of mounting a juvenile tortoise, while thrusting and emitting guttural, scraping noises. He was approximately four years old. On 2 July 1979 this male was observed mounting the sibling female in the outside pen. It was not possible to observe if penetration occurred. Numerous mountings and copulation attempts were observed from 1979 to 1982 with the peak sexual activity occurring in the months of June and July when the specimens were outside. Mountings were stimulated by spraying the specimens with a fine mist from a garden hose while they were in the outside pen.

The female produced three or four broken eggs in the indoor pen on 28 December 1979. At this time she was approximately 6.5 years old and weighed 3.63 kg. She laid single eggs on 31 December 1979, 5 January, and 9 January 1980. The eggs were broken as they were extruded from the female's cloaca. Possibly the eggs were too thin-shelled or the carapace-plastron opening was too narrow to allow the eggs to pass. Between 28 December 1979 and 28 September 1982 the female produced 11 clutches of eggs totaling 54 or 55 eggs (Table 1). All of the eggs were laid in the outside pen with the exception of those produced in December 1979 and January and December 1980.

Incubation periods ranged from 135 to 202 days with an average of 156 days. Rowe and Janulaw (1971) gave average incubation periods of 116-145 days for clutches of leopard tortoise eggs. The average incubation period of the clutches mentioned by Rowe and Janulaw (1971) was 132 days. Klemens (1974 and unpublished data) gave incubation periods of 120-185 days for eggs from one female and 137-202 days for eggs from the mother of the F1 female. Flint (1977) gave incubation periods of 152, 158, and 182 days for eggs from the same clutch. Hine (1978) gave incubation periods of 111-177 days for a single clutch. Cairncross (1946), Bowker (1926), and Archer (1948) reported on eggs laid in the ground and left *in situ* to hatch. Cairncross (1946) mentioned an egg laid on 20 March 1940 which was exhumed on 29 December 1940 after an incubation period of 275 days. A living embryo was found inside the egg. Bowker (1926) discussed a clutch which took 14 months to hatch. Archer (1948) stated that eggs laid in early spring may hatch in eight months. Archer (1948) also stated that eggs laid late in autumn may take up to 18 months to hatch if the summer after oviposition is short and cool.

Eggs incubated in incubators appear to have shorter incubation periods than eggs left in the nest to hatch.

ACKNOWLEDGMENTS

The authors thank Susannah Coakley and Ruth Klemens for their assistance in the care of the tortoises and our wives, Kathleen Coakley and Nicole Klemens, for their patience during this project. We thank Andy Main for assistance with library research and Thomas Prescher for aid in design and construction of tortoise pens. Sandy's Fruit and Vegetable Emporium (Mystic, Connecticut) provided fruits and vegetables.

NOTES ON THE REPRODUCTIVE BIOLOGY OF THE EYELASH VIPER *Bothrops schlegeli*, IN CAPTIVITY

The Eyelash Viper *Bothrops schlegeli* is a species of arboreal pit viper, widely distributed from Southern Mexico to Ecuador and Venezuela (Peters and Orejas-Miranda, 1970). Although common in many parts of its range, information concerning reproduction is scarce in the literature. Antonio (1980) reported on a litter which resulted from a captive-breeding of wild caught snakes.

This paper presents data on five litters (50 neonates) born to three captive-born females. Included are behavioral observations on gestating females, age of attainment of sexual maturity, fecundity with relation to female total length, and coloration of neonates.

Materials and Methods

Male A, from an unknown locality, was received as an adult on 4 August 1978. Male B, and females A and B, captive born on 9 August 1978, to parents from Sula, Honduras (Antonio, 1980) were received as juveniles in February 1979. The snakes were maintained in various sized aquaria in the author's personal collection. On 26 February 1981, the snakes were transferred to the Fort Worth Zoological Park. Female C, captive born on 25 July 1978, to wild-bred parents from San Jose Province, Costa Rica (Finstrom, pers. comm.) was received on 15 December 1981 at the Fort Worth Zoological Park.

The snakes were housed on exhibit in a 91.4 cm fiberglass enclosure (Hulsey, 1973), and on reserve in screen-topped glass aquaria. Props in the exhibit included gravel substrate, rocks, plastic plants, dried leaves branches and water bowl. The aquaria on reserve were provided with newspaper substrate, plastic plants, branches and water bowl. The snakes were offered freshly killed laboratory mice of various sizes, every 1-2 weeks. Ambient temperature was maintained between 24.4 and 29.4° C. Lighting was provided by skylights and a 20 watt Vita-lite® tube (Durotest Corp.). A 50 watt infrared spotlight (Sylvania Corp.) was placed above one corner of the exhibit to provide additional heat during daylight hours for gestation. The snakes were misted 1-3 times per week and often drank water from their body coils.

Males A and B were first introduced into the exhibit housing females A and B in April 1981. Female C was first introduced 20 December 1981. The males were switched between exhibit and reserve cages at intervals of three days to three weeks, while females remained on exhibit.

Neonates were weighed within one week, *postpartum*, on an Ohaus, triple-beam balance. Adult females and neonates were measured within one week, *postpartum*, using the squeeze box technique (Quinn and Jones, 1974). The young were housed in plastic containers of various sizes, with props similar to those of the reserve aquaria. The juveniles were offered defrosted frogs or frog parts *(Acris crepitans)* after their first shed (1-10 days, *postpartum*). Stubborn individuals were coaxed with live frogs *(Acris)* and lizards *(Tropidurus)*. The snakes that fed (46) were switched to pre-weanling mice or parts of mice within 1-12 weeks.

Table 1. Birth dates, age of females at parturition, time intervals between litters, total length (mm) and weights (g) of neonate *Bothrops schlegeli*.

	Female A Litter #1	Female A Litter #2	Female B Litter #1	Female B Litter #2	Female C Litter #1
Date	7 Nov 1981	17 July 1982	26 Dec 1981	5 Aug 1982	20 June 1982
Age	3 yrs 90 days	4 yrs 33 days	3 yrs 139 days	4 yrs 59 days	3 yrs 329 days
Interval		8 mos 10 days		7 mos 10 days	
Total length (mm) neonates ($\bar{x}$)	165-190 ($\bar{x}$=181)	147-207 ($\bar{x}$=188)	170-186 ($\bar{x}$=177)	190-211 ($\bar{x}$=198)	182-190 ($\bar{x}$=186)
Weight (g) neonates ($\bar{x}$)	2.1-3.1 ($\bar{x}$=2.8)	1.3-3.5 ($\bar{x}$=3.0)	2.4-3.2 ($\bar{x}$=2.7)	2.8-3.2 ($\bar{x}$=3.0)	2.3-3.1 ($\bar{x}$=2.6)

Results

All observations took place during daylight hours. Although copulation was not observed, females appeared gravid 4-5 months *prepartum*. During this time they positioned themselves on branches within 9-27 cm from the spotlight, while males generally positioned themselves at random throughout the exhibit. Temperature 9 cm below the spotlight was 29.4° C. while the opposite side of the cage was 24.4° C. Cessation of feeding began 4-5 months *prepartum* for the females, with the exception of two individuals that fed once during that period, while males fed consistently. Females began feeding again within one week after birth took place. Birth dates, age of females at parturition, time intervals between litters, total lengths (mm) and weights (g) of neonates, are given in Table 1. Total length of *postpartum* females and number of neonates are given in Table 2.

Table 2. Females' total length *(postpartum)* and number of neonates in *Bothrops schlegeli*.

	Female C Litter #1	Female A Litter #1	Female B Litter #1	Female B Litter #2	Female A Litter #2
Female length (mm) *postpartum*	630	686	691	700	725
Number neonates	6	8	9	10	17

Coloration of neonates was equally divided (25:25) between two basic color phases: a dark phase ranged from deep green to gray-green background, and a light phase ranged from dull yellow to tan background. The adult males had background color which ranged from deep olive green to deep green while the females ranged from light salmon to bright yellow. Neonate color was drab with poorly defined pattern in comparison to the adults. The tips of the neonates' tails were white. As they grew, their colors and pattern became more vivid and distinct, and the tail tip coloration faded.

Observations and Discussion

The above observations of *B. schlegeli* in captivity indicate that 1) females can reach sexual maturity at less than three years (Table 1), 2) females can produce more than one litter *per annum* (Table 1), 3) gestating females generally fast and position themselves close to a heat source when given the opportunity (similar behavior has been seen in other live-bearing snakes of the families Crotalidae and Boidae [pers. obs.]), and 4) there is a direct correlation between litter size and total length of the female (Table 2).

The observation that females can produce more than one litter *per annum* differs significantly from wild populations of viviparous snakes studied by Fitch (1970) who suggests that there are relatively few live-bearers that have the capacity to ovulate again soon after the birth of a litter and that the interval between successive ovulatory periods is most typically a year or more.

The direct correlation between litter size and total length of the female (Table 2) is supported by Fitch (1970) who found similar results in almost every squamate species that has been thoroughly investigated.

It is also interesting to note that the above litters were born in every season of the year, but only between 20 June and 26 December. Additional data are necessary before the exact nature of the reproductive cycle in *B. schlegeli* can be determined.

ACKNOWLEDGMENTS

I express gratitude to the following people: Matt Finstrom for supplying data, Gary Carl and James B. Murphy for reviewing the manuscript, and Steva K. Blevins for typing. I am especially grateful to the staff of the Department of Herpetology, Fort Worth Zoological Park for assistance and to my wife Joanna for encouragement and helpful comments. Specimens will be placed at the University of Texas at Arlington Collection of Vertebrates upon their deaths.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Houston Zoological Gardens, P.O. Box 1562, Houston, Texas 77001.

ANURA

BUFO AMERICANUS (American Toad). **ESTUARINE HABITAT.** On 19 April 1982, we found a breeding congregation of at least 50 *Bufo americanus* in a tidal marsh, the Iona Island Marsh on the Hudson River in the Town of Stony Point, Rockland County, New York. The toads were concentrated in the shallower portions of the tidal creeks on both sides of the fill causeway crossing the marsh, in a sheltered area some distance from the open estuary. We watched the toads from 1230-1330 h, around low tide, when they were in little pools and sheets of water *ca* 3-20 cm deep. Many toads were calling. About half of the toads seen were in amplexus. One amplexed pair was on a bare mudflat with the female sunk about halfway into soft mud. There were many strings of toad eggs in the pools; a few strings were stranded by the low tide on bare mud and two strings hung over snags 30 cm above water. Large numbers of killifish (*Fundulus heteroclitus* and *F. diaphanus*) in the pools seemed to ignore the toad eggs. Mean tide range at this locality is *ca* 0.9 m, and the water varies from fresh to slightly brackish seasonally.

On 23 April EK visited the marsh at about high tide (0940 h) and again at low tide (1530-1730 h). No toads were seen or heard. The eggs were still in the tidal creeks. *Fundulus heteroclitus* picked gently at egg masses but seemed to be ingesting algae or detritus rather than eggs. A water sample collected at low tide had a salinity of 300 mg/1 or less than 1% seawater strength. Another sample from the breeding site collected 26 May 1982 had salinity 585 mg/1. (Samples were analyzed by Hach C1 method by Michael Rosenthal, Bard College Chemistry Department.)

Eggs collected 23 April began hatching in captivity the same day. Small live tadpoles offered to *F. heteroclitus* in an aquarium were repeatedly mouthed and spat out — 1 tadpole might have been swallowed. All of the tadpoles died 13 May, apparently from overheating, at a head-body length of about 4 mm and a normal appearance.

Neill (1958, Bulletin of Marine Science of the Gulf and Caribbean 8(1):1-97) summarized reports of several *Bufo* species in tidal and/or brackish water habitats, but did not mention *B. americanus*. Although Iona Island Marsh is tidal all year, the water is normally fresh or nearly so in spring when the tadpoles would be developing. Few amphibians (both species and numbers) have been found in the tidal Hudson River. Limiting factors could include salinity, tidal fluctuation, generalized PCB pollution, or presence of many potential predators. Single calling male *B. americanus* have been heard in strictly freshwater tidal wetlands farther up the Hudson, but choruses, amplexed pairs, or eggs have not been found.

SAURIA

ANOLIS CAROLINENSIS (Green Anole). **PREDATION.** On 27 and 28 March 1966 at Griffis Camp, 18 km E. of Fargo, Clinch County, Georgia, a large migratory flock of robins, *Turdus migratorius*, was very much in evidence. On several occasions robins were observed to kill and eat individuals of *Anolis carolinensis*. The lizards were grasped in the beak of the robin, killed or stunned by several sharp biting motions, and swallowed whole in a manner similar to killing and swallowing an earthworm.

Although the staple foods of robins consist of vegetable matter and insects such as beetles and caterpillars (Bent, 1949. U.S. Nat. Mus. Bull., No. 196, 454 pp), they may opportunistically feed upon small vertebrates as trout fry (Michael, 1934. Condor 36:33-34). At such times large, normally transient, migratory or wintering flocks (of robins and presumably other birds) could severely impact local populations of small lizards or other small herpetofauna.

Appreciation is extended to Robert Powell for critically reviewing this note.

Submitted by **DONALD D. SMITH,** Dept. of Pathology and Oncology, University of Kansas Medical Center, 39th and Rainbow, Kansas City, Kansas 66103. ●

CROTAPHYTUS COLLARIS (Collared Lizard). **REPRODUCTION.** Fitch (1970. Univ. Ks. Mus. Nat. Hist., Misc. Publ. No. 52, 247 pp) reported clutch sizes for *Crotaphytus collaris* ranging from 1-12 eggs, based on over 50 records. Here two additional clutches of seven and 13 eggs respectively are reported. A specimen collected 25 June 1962 in Independence, Jackson County, Missouri, and measuring 98 mm (snout-vent length) delivered seven eggs on 9 and 10 July 1962. These eggs averaged 19 X 11 mm (17-20 X 10-12 mm).

The other specimen, captured 17 km E. of Olnay, Archer County, Texas, on 10 May 1975, delivered 13 eggs on 29 May 1975. These eggs also averaged 19 X 11 mm. The snout-vent length of this female was never measured, but she weighed 47.5 g on 24 May and 28.2 g on 29 May after delivery — a loss of 19.3 g or about 1.5 g per egg. These eggs were placed individually on dampened paper towels in plastic sandwich bags, and incubated at temperatures fluctuating between 24 and 30° C. On 4 August 1975, three of the eggs (23%) hatched 86 days after deposition. Fitch (1956. Univ. Ks. Publ., Mus. Nat. Hist. 8(3):213-274) reported possible incubation periods of from 51 to 82 days depending on temperatures. Measurements of hatchlings were taken on 6 August 1975 (Table 1).

Table 1. Length, weight, and sex of 3 hatchling *Crotaphytus collaris*

S-V Length mm	Tail Length mm	Weight g	Sex
32	46	1.7	F
31	44	1.1	F
33	52	1.5	F

Appreciation is extended to Robert Powell for critically reviewing this note.

SERPENTES

CORALLUS ENYDRIS ENYDRIS (Garden Tree boa). **FOOD.** Groves (1980, Brit. J. Herp. 6:89-91) reviewed instances of ovophagy in a number of varieties of mainly terrestrial boids. This report describes post-parturient behavior in an arboreal species, *Corallus enydris enydris*, which ingested her own freshly deposited egg masses. Thirteen masses and three stillborn young were deposited between 0300-0600 h, 16 May 1979. The snake was

observed at 0600 h with one egg mass in her mouth. After swallowing, she investigated the perimeter of the aquarium. Tongue-flick rate was approximately 1/sec until she contacted a second egg mass. She then bit, constricted, and swallowed the mass. The female repeated this procedure with six additional eggs during an 80 min period. The remaining six eggs and stillborn young were then removed from the enclosure. The six masses were examined and determined to be infertile. Constricting behavior suggests that the normal feeding sequence (grasping, killing and swallowing) was followed even though such behavior was presumably unnecessary.

Food had been offered throughout the gestation period. One meal of two mice, each weighing 25 g, was accepted on 17 March 1979, 90 days after the last observed copulation. The meal previous to the first observed copulation was on 8 December 1978. The cessation of normal feeding behavior in gravid snakes for the gestation period has been observed by the author on several occasions. This is by no means the rule, as I have observed *Bitis arietans* to feed throughout the gestation period. Pressures of infertile eggs and/or the developing embryos on the viscera may halt feeding behavior.

I thank Bern W. Tryon for editorial comment.

Submitted by **TRACY J. MILLER,** Buffalo Zoological Gardens, Delaware Park, Buffalo, New York 14214. ●

ELAPHE SUBOCULARIS (Trans-Pecos Rat Snake). **COLORATION.** An *Elaphe subocularis* collected by the authors 1.6 km WNW of Castolon, Big Bend National Park, Brewster County, Texas, on 14 July 1966 exhibits an aberrant color pattern. The specimen differs from normally patterned *E. subocularis* in lacking the dark H-shaped markings and black, anterior, dorso-lateral lines characteristic of the species (Figure 1). The resulting pattern consists of 22 somewhat diamond-shaped blotches on the body and seven on the tail. They are lighter in color than normal and difficult to distinguish on the preserved specimen.

The female measures 1020 mm (total length), 142 mm (tail length) and has 275 ventrals, 72 subcaudals, 10 supralabials, 14 infralabials, 1 preocular, 2 postoculars, and 7-6 lorilabials. The anal plate is divided. Diagnostic characters are within the ranges given by Worthington (1981. Cat. Amer. Amphib. Rept: 268.1-268.2). Dorsal ground color was a dull yellow in life, and within the color range given by Wright and Wright (1957. Handbook of Snakes, Vol. 1. Comstock: p 256).

Figure 1. Aberrant dorsal pattern of an *Elaphe subocularis* from Brewster County, Texas.

This specimen is similar to a female, also captured in Brewster County and depicted by W. E. Lamoreaux (1980. Herp. Review 11(4): 117). The patterns of both of these specimens apparently resemble the posterior portion of a male (Chicago Natural History Museum # 38943) without locality data described by Dowling (1957. Univ. Mich. Mus. Zoo., Occ. Papers, No. 583:1-22). The two Brewster County specimens verify the presence of *E. subocularis* with depauperate dorsal patterns from within currently defined range.

The specimen has been deposited in the Bobby Witcher Memorial Collection (BWMC 01019) housed at Avila College, 11901 Wornall, Kansas City, Missouri 64145. Appreciation is extended to Robert Powell for critically reviewing this note.

Submitted by **DONALD B. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th and Rainbow, Kansas City, Kansas 66103 and **HARRY L. GREGORY,** Hutchinson-Reno County Zoological Society, Inc., P.O. Box 444, Hutchinson, Kansas 67501. ●

STORERIA DEKAYI WRIGHTORUM (Midland Brown Snake). **COLORATION.** On 15 April 1982, an albino *Storeria dekayi wrightorum* was found underneath a rock by a junior high school student while working in a flower garden in a residential section of West Grove, Jefferson County, Alabama. The specimen, a subadult female, had a total length of 232 mm and an S-V length of 187 mm.

When alive, the snake had pink-red eyes. Its ground color was creamy white, with a slightly brighter dorsal stripe. The body pattern was greatly reduced and lighter in coloration than normally-pigmented specimens of *S. dekayi wrightorum*. The dorsal stripe was flanked by a row of light brown spots on each side, but the spots were not fused to form crossbars, as is evident in 90% of *S. dekayi wrightorum* from Alabama (Mount, 1975, The Reptiles and Amphibians of Alabama, Auburn Univ. Agricultural Experiment Station, Auburn). Only a few faint rusty flecks were present along the sides, and some small dark spots were found along the edges of the anterior ventral scales. The normally dark-pigmented regions of the head (parietal scales, temporal bar, and spot on labials below the eye) were a light pink-brown.

According to the reviews of Hensley (1959, Publ. Mus., Mich. State Univ. 1(4):133-159) and Dyrkacz (1981, SSAR Herp. Circ. 11), three other albinos of this species have been reported previously in the literature. Hensley (1959) noted an albinistic individual from Pennsylvania, but did not describe it. Smith (1961, The Amphibians and Reptiles of Illinois, Ill. Nat. Hist. Surv. Bull. 28, Urbana) reported a cream-colored subadult from Illinois with pink dorsal spots, and Thrall (1971, Trans. Ill. Acad. Sci. 64(4):400) described another from the same state as being pink with pinkish-brown dorsal spots.

Figure 1. Dorsal view of albino *Storeria dekayi wrightorum* from Jefferson County, Alabama.

The animal described here was maintained in captivity for a short time, but refused to eat and was preserved. The specimen has been deposited in the University of Alabama in Birmingham Vertebrate Museum (VM-UAB 0383).

Submitted by **KEN R. MARION,** Biology Department, University of Alabama in Birmingham, Birmingham, Alabama 35294 and **GRADY CHANDLER,** P.O. Box 692, Bessemer, Alabama 35021. ●

TESTUDINES

CHELYDRA SERPENTINA (Common snapping turtle). **MORPHOLOGY.** In August, 1982, while completing a three year study on the effects of rotation on egg viability in turtles, an unusual specimen was noted. A two-headed *Chelydra serpentina* was found by Thomas McFarland among the day's hatchlings from a group of 240 eggs under observation. This turtle had successfully hatched from the egg without help and appeared alert. A snapping turtle of similar description evidently lived in the 1930s. It grew to a weight of 7½ lbs. by the age of five-and-one-half years. After the death of its owner, Mrs. Grace Wiley, the turtle was lost to follow-up (Campbell, H. 1967. Once upon a time. Int. Turtle and Tortoise Soc. J. 1(4):24-29). A photo of this turtle (named "nip and tuck") is quite similar to the speciman presently described. There are two heads, equally active and alert, and a somewhat diminutive shell structure. Other observations regarding the present specimen (Fig. 1) are a kinked tail and a projection of tissue between the heads that yields speculation of additional nervous tissue. In addition the plastral opening for the yolk sac has failed to close at all since hatching. The behavior of this specimen is similar to a two-headed *Graptemys pseudogeographica* kept at the Staten Island Zoo in 1966 (Clement, H. 1967. Are two heads better than one? Int. Turtle and

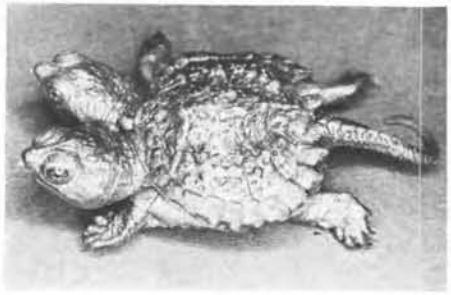

Figure 1. Dorsal view of 2 headed *Chelydra serpentina* hatched under controlled conditions.

Tortoise Soc. J. 1(2):4-5). As in that specimen the heads are truly independent of each other. They demonstrate no cooperation or unity of intent. They will fight over food and try to guide the body in opposite directions simultaneously if divergent food items are present. This behavior has not extinguished with time; that is, the heads will simply not learn to cooperate. However, each head appears to be quite capable of learning on its own. Both heads have well developed snapping reflexes and have adjusted to hand feeding. Such conflict of motion also precludes normal righting behavior. Each head attempts to right the turtle in an opposite direction when the animal is placed on its carapace. Hence, it is unable to right itself, even over prolonged periods.

As well developed and independent as cranial nerve function appears to be in the heads, a similar lack of cooperation might be expected in the limbs. Indeed, it seems each foreleg is controlled by the ipsilateral head during times of conflict (*i.e.* divergent food sources). Yet, when the two heads agree on a course of action, the animal moves in a frog-like manner with all the limbs jerking in unison.

These behavioral alterations translate into unusual difficulties in caring for the animal. To avoid drowning the water must be kept only as deep as the carapace is high. Since the turtle is incapable of coordinated motion over complex terrain it must be kept in a gently sloping, small, flat-bottomed container so it can move under a sunning lamp when desired. Since the heads do not have the use of forelegs to tear food, each head must be fed separately with pieces of food small enough to be eaten whole. It appears that feeding 2-3 times a day achieves the best results. Growth after five months has been about 70% normal for a hatchling *C. serpentina*.

NEWSNOTES

ANNOUNCEMENT TO THE MEMBERSHIP OF THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The Association of Systematics Collections (ASC) is currently compiling an annotated checklist of the amphibians of the world, the second in a series of annotated checklists started by *Mammal Species of the World* (published in 1982). The amphibian checklist is scheduled to be published in early 1984 as a joint venture of ASC and Allen Press, Inc. Information to be carried in the checklist for each species includes: current scientific name (based on most recent literature), original name, author, date, and literature citation of description, museum registration number of primary type(s), type locality, and distribution. Comments citing pertinent reviews, revisions, and alternative systematic opinions will be presented with appropriate bibliographic citation. In addition, regulatory status under the Convention on International Trade in Endangered Species (CITES) and the United States Endangered Species Act (US-ESA) will be included in the published volume.

The checklist is not intended to be an 'official' list of names, nor is it an attempt to 'standardize' amphibian systematics; instead the checklist is designed to be a reference volume for practicing systematists, a source of 'current' taxonomy for non-systematists, and a source of regulatory information for those who import and export amphibians. An important difference between the ASC checklists and previous ones is that the ASC checklists represent the efforts of a community, and are not intended to promote the proprietary views of any one segment of the systematic community over another. We think that by detailing systematic controversies and making the lacunae in our knowledge apparent, the ASC checklists will promote systematic research where it is most needed. In addition, unlike other checklists, the ASC checklists can be computer sorted to accommodate requests through ASC and will be updated at predictable intervals to ensure that they do not fall too far behind current nomenclature.

Sections of the amphibian checklist are currently being completed, corrected, and augmented by individually recruited contributors. The accuracy and content of this draft checklist will be ensured by a process of open review, in which reviewers can add comments (from published sources) and correct errors. Like the contributors, the reviewers will be attributed by name with the section(s) of the checklist on which they have worked.

In order to guarantee the accuracy and completeness of the published checklist and assure that it best serves the needs of herpetologists, ASC wishes to enlist the cooperation of the members of the Society for the Study of Amphibians and Reptiles. If you are willing to review taxonomic and/or geographic sections of the checklist, please write to Darrel Frost (Editor/Compiler), Association of Systematics Collections, Museum of Natural History, The University of Kansas, Lawrence, Kansas 66045, USA, and inform him on which taxonomic sections and/or geographic regions you would like to work. ●

ERRATA

Alvin L. Braswell was erroneously included as an author on the article "Lampreys in the diet of the hellbender *Cryptobranchus alleganiensis* (Daudin), and the Neuse River waterdog *Necturus lewisi* (Brimley)" in HR 14(1), 1983 - removal requested by Alvin L. Braswell. ●

LOCALITY RECORDS OF MINNESOTA HERPS WANTED

Minnesota locality records of all species of amphibians and reptiles in the state are sought to update distribution maps as part of a nongame project sponsored by the Minnesota Department of Natural Resources. Records from regional or private collections, likely to be otherwise overlooked, are of particular interest. For more information and a checklist of the species occurring in Minnesota, please contact Jeffrey Lang, Department of Biology, University of North Dakota, Grand Forks, N.D. 58202. (701) 777-4564, 772-0227. ●

REPORT ON A SYMPOSIUM ON INTRODUCED SPECIES, LONDON, ENGLAND, AUTUMN 1982

A Symposium on Introduced Species was held jointly by the British Herpetological Society (BHS), Fauna & Flora Preservation Society (FFPS) and Mammal Society on Saturday, 27th November 1982, in the meeting Rooms of the Zoological Society of London, Regent's Park, London NW1.

The Morning and Afternoon Sessions were chaired respectively by Dr. J.F.D. Frazer, formerly of the Nature Conservancy Council (lately President of the BHS, Treasurer of the Mammal Society) and Mr. I. J. Linn, Department of Zoology, University of Exeter (Chairman of the independent Working Group on Introductions of the UK Committee for International Nature Conservation). The eight papers included four each on herpetofauna and mammals. After an introductory paper by Sir Christopher Lever, the herpetological papers included:

Dr. T.J.C. Beebee (Department of Biology, University of Sussex): Green frogs and other illegal immigrants

Mr. R.E. Honegger (Curator of Herpetology, Zürich Zoo, Switzerland): Intoduced amphibians and reptiles and their influence on native biota, with reference to *Bufo marinus* (read by M.R.K. Lambert)

Mr. Q. Bloxam (Jersey Wildlife Preservation Trust): The potential of re-introducing *Leiolopisma telfairii* in the Mascarenes, Indian Ocean

Mr. K.F. Corbett (BHS Conservation Committee and Chairman, Societas Europaea Herpetologica Conservation Committee): Conservation of declining UK herpetofauna - successful re-introduction techniques.

The Symposium followed an earlier one, jointly held by the BHS and Mammal Society, in 1963. The papers presented are to be published in summarized form by *Oryx*, the journal of FFPS, in 1983.

M.R.K. LAMBERT
British Herpetological Society, London

EVOLUTION IN THE GALAPAGOS ISLANDS - REPORT ON A SYMPOSIUM, LONDON, 1982

A one-day Symposium 'Evolution in the Galapagos Islands' was held by the Linnean Society of London, in association with the Charles Darwin Foundation, on Tuesday 9th December 1982. The symposium took place in the Lecture Theatre of the Linnean Society (where meetings of the British Herpetological Society are held), Burlington House, Piccadilly, London W1, England. The meeting was chaired in the morning by Professor R.J. Berry (University College, London), 1982 President of the Linnean Society and Editor, the *Biological Journal of the Linnean Society*, and in the afternoon by Dr. P. Kramer (Essen, F.R. Germany), President of the Charles Darwin Foundation (CDF) and Dr. O. Hamann (Denmark), European Secretary of the CDF.

The talks ranged from a general consideration of 'islands and evolution' (Professor A.J. Cain, University of Liverpool), through the geological formation (Dr. B.R. Rosen, British Museum Natural History), genetical processes, specific vertebrate groups, effects of the introduction of an ant on other invertebrates (Dr. Y. Lubin from U.S.A., CDF) and colonization by flora (Professor D. Porter, University of Virginia, U.S.A.), to the impact of man on fragile ecosystems (Dr. P. Kramer). Four of the twelve papers were on or involved an herpetological interest (giant tortoises):

Dr. F. Sulloway (Harvard University, Cambridge, Massachusetts, U.S.A.): 'Darwin and the Galapagos'
Dr. J. Patton (University of California, Berkeley, U.S.A.): 'Genetical processes in the Galapagos'
Dr. T. Fritts (U.S. Fish & Wildlife Service): 'Tortoises'
Dr. H. Snell (University of Colorado, Boulder, U.S.A.): 'Iguanas'

The Symposium constituted part of the Linnean Society's Centenary Commemoration of Charles Darwin's death in 1882 (19th April, in Kent, buried seven days later in Westminster Abbey). The papers will be published in full, together with others that the symposium time did not allow, in 1983 (August) in part 1 of the second volume *(20)* of the *Biological Journal of the Linnean Society*. A hard cover edition will also be prepared for wide circulation.

It may also interest members to know that nine essays on Charles Darwin: the man, his theory and his life, were published in February 1982 in *Biological Journal of the Linnean Society* 17(1). This journal, already emphasising the processes of organic evolution in the broadest sense, is to concentrate on this sphere from 1983.

BOOK REVIEWS

Frösche und Kröten, by Rainer Schulte, 1980. Verlag Eugen Ulmer, Stuttgart. 240 pp. 38 color photographs. 62 black and white photographs and line drawings. Price: 38 DM.

Europeans, particularly the Germans and the Dutch, have long been known for their interest in keeping reptiles and amphibians in terraria, and much of the recent European literature on the breeding behavior of these animals has appeared in several high quality aquarium and terrarium magazines published in Germany and the Netherlands. These papers often contain useful information and generally are illustrated with excellent color photographs which cannot be included in most scientific journals. Rainer Schulte's book on frogs and toads is a product of this tradition.

Most American books aimed at terrarium enthusiasts and amateur herpetologists are overpriced and poorly produced, filled with inaccurate information, and illustrated with poor quality, frequently mislabelled photographs. Schulte's book, on the other hand, is a high quality hard-bound production filled with useful information and many beautiful color and black-and-white photographs. It is expensive by American standards (around $20) and presently available only in a German language edition. Nevertheless, for those who read German, it should be a worthwhile investment.

The first 98 pages are devoted to a general introduction to anuran classification and biology, including sections on breeding biology, vocalizations, and poisonous skin secretions, and a very detailed discussion of maintaining frogs and toads in captivity. Here Schulte describes types of aquaria and terraria suitable for different species, and he discusses in detail such topics as temperature and moisture conditions, light regimes, and feeding requirements. Also included are methods for rearing tadpoles through metamorphosis, methods of eliciting breeding behavior in captivity, equipment and techniques for collecting insects to feed captive animals, diagnosis and treatment of amphibian diseases, methods for recording vocalizations, and a variety of other practical information. These features of the book should be useful for graduate students and researchers interested in maintaining anurans in the laboratory.

The remainder of the book is devoted to accounts of individual species which the author has personally maintained in captivity, and in many cases, observed in the field. Although the book is subtitled "Tropical and Native Frogs in the Terrarium," the emphasis is very much on tropical forms; European species are discussed in only four pages at the end. In each species account, the author describes morphology and color pattern, geographical distribution, general ecology and natural history, breeding biology, and behavior in the field and in captivity. Coverage is somewhat spotty and mainly reflects the author's own interests. His specialty is the family Dendrobatidae; many species in this family are described in detail and illustrated with spectacular color photographs. On the other hand, only three species of *Hyla* are given separate treatment. Overall, the species described tend to be colorful, poisonous species most frequently imported by European pet dealers.

Several features of the book may be annoying to professional herpetologists. Species accounts are arranged alphabetically by genus, rather than taxonomically. Hence descriptions of the dendrobatid genera *Colostethus, Dendrobates,* and *Phyllobates* are in different parts of the book, rather than together for easy comparison. Literature citations are somewhat sloppy and heavily weighted toward articles in German aquarium magazines, with only occasional reference to recent field studies. Several authors cited in the text do not appear in the bibliography. Perhaps the most serious deficiency is that many statements appear without a clear indication of the source of information. Many statements apparently are derived from the author's own observations, but the lack of explicit attribution makes it hard for readers to evaluate the reliability of the information.

Despite these reservations, I think the book contains much useful information not readily available elsewhere, and the color photographs alone will make it a worthwhile purchase for anyone interested in the diversity of tropical frogs.

KENTWOOD D. WELLS

University of Connecticut
Storrs, Connecticut 06268

Natural History of Amphibians and Reptiles of Wisconsin, by Richard Carl Vogt. 1981. Milwaukee Public Museum. 205 pp. ISBN 0-89326-060-6. $25.95.

In recent years a number of regional and state herpetological handbooks have become available, most of good quality. Ideally, a geographically localized volume on reptiles and amphibians should be of value to the general public, as well as to the professional herpetologist. Dick Vogt has now completed such a volume for Wisconsin, and it is certainly an impressive and successful contribution.

In Natural History of Amphibians and Reptiles of Wisconsin, Vogt begins with a history of herpetology in Wisconsin, and a description of the state's physiography and vegetation. Wisconsin is in an interesting geographical position from a herpetological standpoint, with the Mississippi Valley allowing herp species a corridor from the south, while prairie species enter from the west, boreal species from the north, and eastern species from the lower Great Lakes. In this account, the author has sifted out many old, questionable records with clearly explained justifications.

Of great value here are the identification keys to adult and larval amphibians and to reptiles. While useful identification keys must often resort to somewhat technical terminology, Vogt has included explanatory diagrams where necessary. Terms not illustrated can usually be found in the glossary.

The heart of any regional guide is the species accounts. In this book, the life history of each species is described fully, with sections on description, range, habitat, and habits (includes reproduction). All species are illustrated with color photographs, usually a large portrait and several smaller plates showing details of identification, eggs, young, *etc.* Unfortunately, some of the photos—particularly the smaller ones—appear either too dark or too light (under- or over-exposed).

The range of each species is illustrated, by site and museum specimen records, on a county map of Wisconsin. A small inset map of North America shows the general range for the species, based on the maps in Roger Conant's Field Guide to Amphibians and Reptiles of Eastern and Central North America (Houghton-Mifflin, 1975). A minor criticism here is that these small maps were reproduced so faintly as to be practically invisible for some species.

The author's writing style is readable and clear. Dick's occasional personal anecdotes and "collecting stories" liven up the text and add interest. As previously mentioned, a glossary is included, as well as a literature cited and reference section. A general index, and useful indices to herptile predators and foods, round out the book.

It is obvious that a great amount of time and effort went into this project, and the result is a scholarly, yet colorful and readable, contribution to American herpetology. This book may well have set a new standard for state and regional herpetological handbooks.

Bloomfield Hills, Michigan 48013

Veterinary Biology and Medicine of Captive Amphibians and Reptiles, by Leonard C. Marcus, D.V.M., M.D. 1981. Lea & Febiger, Philadelphia.

Herpetological medicine is a specialty that is in its infancy. The slow growth in the popularity of herpetological medicine is due to a number of factors. Few amphibians or reptiles are of great economic importance, and the use of these classes in laboratory situations remains limited when compared to other laboratory species. In zoos, herpetological collections are variable in both size and diversity and even as pets they are kept on an infrequent but increasing basis. The literature itself is limited and often found in less familiar publications. The limited practice possibilities and literature have restricted the veterinarian from becoming involved in this area. The classes Reptilia and Amphibia are large and diverse and their biology, husbandry and medicine are equally diverse. The slow progress.of this specialty has generated a science filled with extrapolations and case reports with few innovative clinical advances or well documented syndromes.

Doctor Marcus' book is the first publication in over a decade to attempt a comprehensive update of this field. The book is divided into three major sections. Each section is intended to build upon the earlier section and move logically from the normal animal through the clinical evaluation, diagnosis and treatment of the specimen.

The first section, "The Normal Amphibian and Reptile," focuses on the anatomy and physiology of these two classes. The information for the most part is general and allows the reader to gain an introductory exposure to the normal animal. Some caution must be exercised in this section to recall the danger of generalizing for classes as divergent as these.

In the second section, "Principles of Husbandry and Veterinary Care of the Herpetofauna," the author covers a broad spectrum of topics from environmental needs to anaesthesia. The breadth of knowledge in these areas is considerable but unfortunately it is treated in very general terms making this the weakest portion of the book. The information that is provided should be considered introductory and not as the state of the art. The clinician should recall the growing importance of the captive environment and its overall effect on the health of the animal.

The greatest portion of the book focuses on the "Specific Diseases of the Herpetofauna." This section is by far the book's strong point. It is well written with an extensive bibliography covering the infectious and parasitic diseases. Doctor Marcus' familiarity and concern with the zoonoses is particularly helpful when considering herpetological diseases from a public health standpoint. Disease transmission from species to species and to man is considered for many of the reported conditions. The reader becomes immediately aware that a major difficulty in dealing with the diseases of the herpetofauna is an overall lack of depth in many major areas. Quite often the total number of captive specimens is few, the frequency of the clinical syndrome is low, and many diagnoses are made at post mortem.

In a field of growing interest with a scant literature, Doctor Marcus' book is well worth the price for the student, veterinarian, researcher and professional herpetologist. The work reflects the slow progress of herpetological medicine both in institutions and in private practice and should lend itself to stimulating interest in the area and serve as a basic reference for future comprehensive works.

Leopard Frog Populations and Mortality in Wisconsin, 1974-76, by Ruth L. Hine, B. L. Les, and B. F. Hellmich. 1981. Technical Bulletin 122. Dept. of Nat. Resources, Madison, Wisconsin.

For more than 10 years herpetologists have been concerned that the natural populations of North American frogs such as *Rana pipiens* have been declining. Without accurate baseline data much of the supposed decline has failed to be accurately documented. Nevertheless biologists and professional frog collectors with extensive field experience have raised a warning and implicated chemical contaminations of the frog's aquatic habitat as the cause of the decline.

This timely article represents the first attempt to obtain precise information about the status of natural populations of *Rana pipiens.* The project started in 1974 and concluded in 1978. It involved a statewide survey and an intensive study of the east central counties of Wisconsin along Lake Michigan. Data were obtained on number and quality of ponds, population estimates, breeding ponds, egg mass counts, egg development, mortality and survival, breeding activity, post breeding movements, growth, and mortality during hibernation. Other amphibians associated with *Rana pipiens* were also studied.

The results of the study are alarming: low population numbers, many ponds devoid of any frogs, low survival of the eggs, and high mortality during hibernation. In some areas the mortality at the end of three years was 100%.

The authors were unable to firmly establish the cause of this abnormally high mortality. They did obtain evidence that ruled out disease as a common cause. Degenerative liver changes indicated toxic substance as the causative agent. The authors suggest that Atrazine, a herbicide, may be one of the chemicals.

The implications of this study are alarming. Given all the unfortunate prior examples of the effect of chemical contamination on wildlife, it is sad and disheartening to realize that the Wisconsin situation is probably not an isolated tragedy, but one that is occurring over much of the world. It is clearly time that herpetological societies assume responsibility for publicizing this unnecessary destruction. Herpetologists as students of amphibians should also be the protectors. More studies are necessary and the need to accurately determine the causative agents should have high priority.

The authors are to be thanked and congratulated for this timely and very necessary study.

University of California
Riverside, California 92502

Expedition to Greece 1980, by D. Stubbs, A. Hailey, W. Tyler and E. Pulford. University of London Natural History Society. 1981. Mimeo 136 pp. (Available from Univ. London Union, Malet Street, W.C.I. $9.00 incl. post. or £3.50 + postage).

This report is based on field surveys of tortoises in Greece, principally at Alyki (coastal Macedonia) during July and August 1980. Contents include detailed information on one population of *Testudo hermannii*: morphometry, population sex and age structure, longevity, mortality, density, habitat preference, activity patterns, feeding, breeding and aggression, defence, mobility, effects of fire, and a chilling account of a conservation crisis. The authors also discuss the local distribution and niche separation of *T. hermanii* and *T. graeca*, and provide observations on other reptiles and amphibians at Alyki. Appendices contain lists of species of mammals and birds seen on the expedition.

Descriptions of the itinerary, accounts of financial woes, *etc.*, are irritating and indicate that this report must receive rigorous editing before it can be considered a scientific treatise. Many minor typographical errors and inconsistencies (*e.g.*, 10 Km and 10 km on p. 11) are distracting.

Age estimates based on growth rings are approximate (± 2 years) and some relationships are crude (*e.g.*, females aged as 10 years old varied in length from 95 to 155 mm). Morphometric analyses are presented only in graphic form and statistical comparisons are postponed for a later paper. Weights for juveniles seem to have been recorded inaccurately (*e.g.*, one individual weighed only 5 g, less than that of a tortoise hatchling).

Conclusions of annual mortality rates of 8 to 9% and longevity estimates of about 50 years are difficult to accept because one-third of the tortoises older than 10 years could not be accurately aged. Further, the authors calculated adult male population density (18 per ha) but then added an estimate of females (one-third the proportion of males) and juvenile density (based on few recaptures), obtaining an overall density of 53 to 67 tortoises per ha. This estimate would be a record density for any species of tortoise. We should be cautious in accepting this value until substantiated by further field work, particularly where more reliable measures can be obtained on the number of juveniles in tortoise populations.

So what is worthwhile in this paper? It does contain an appreciable amount of data on 632 *T. hermanii* captured on one 75-ha plot, *e.g.*, sex ratio, a bimodal diurnal activity pattern, weight/length relationships, and size frequency histograms. Graphs and illustrations are plentiful. Considerable information on the ecology of the species is presented, and the data will prove useful for comparisons with other species. The authors unjustifiably dismiss comparisons with North American *Gopherus*, particularly *G. berlandieri* which is ecologically equivalent to Alyki *T. hermanii*.

In the last section, these workers reveal the grim reality of tortoise ecology at this site: deliberately set scrub fires followed by destruction by a bulldozer and a rotavator essentially obliterated the Alyki tortoise population and its habitat. The area was levelled in hopes of building holiday homes.

The expedition members located an excellent study area and collected valuable ecological data on a dense population of Mediterranean tortoises. Although expensive for mimeo release and a preliminary report, serious students of tortoises will want a copy of this important study of *Testudo hermanii*.

Systematic Herpetology: A Synopsis of Families and Higher Categories, by H. G. Dowling and Wm. E. Duellman. 1978 (1974-1978). HISS Publ., New York. 118 accounts. $26.50.

This is a loose-leaf volume with the groups subdivided into their various components, with the basic account being the family. If one selected a typical account each is subdivided into family (or subfamily thereof) with author and date, followed by sections on identification, description, content (usually listing genera plus number of species in each), distribution, fossil record, relationships, life histories, remarks and references. Most accounts are concisely written and informative. There is an index of genera and higher categories.

The copyright date is 1978; also on the front is the date 1974-1978 (on the next page is the notation "with minor revisions 1975-1978"). Each individual account is dated, most are either 1973 or 1974. A number of major papers, even prior to 1975 have not been included. These omissions were not due to lack of space, as in many cases an account ends leaving one-half or more of a blank page. Examples of several important snake papers omitted are the Hoffstetter and Rage (1972) paper on Erycinae, McDowell's (1974) Scolecophidia article and (1975) Anilioidea and Pythoninae article. Very few recent papers (after 1974) are cited. The number of species within each genus is given, however in many cases it is an estimate and in some it apparently involves an error. For example, *Lampropeltis* is listed as having 16 species, the genus *Coluber* as having one, and *Zamenis* 21 (if this is a change in handling of the complex genus "*Coluber*," the authors do not so indicate).

The reference section at the end of each account could be improved. For example the "general references" on reptiles (p. 51.4) has room for more references on the page. Included are two references by Bellairs (1960 & 1970) of which the latter is simply an expansion of the former. Klauber's rattlesnake monograph is included, but the 1956 edition is cited rather than the newer edition. In the lizard family Scincidae there are no references to any of Walter C. Brown's publications. Likewise, I find no references to Broadley's work either in the lizard or snake accounts. Both authors (as well as others) should have some references cited, especially since Dowling (1975) is repeated in at least 11 reference accounts, Romer (1956) in 34, and others numerous times.

A considerable number of drawings are included throughout the book. Most are well done, however, I find myself wishing the authors had used labels or the legend to better show the significance of the drawing. In some cases this was done, but too frequently, for example in figure 31.1, the skull of the leptodactylid frog *Caudiverbera caudiverbera*, all that is indicated is that it is a lateral view of the above frog. Probably to the "frog anatomist" this figure plus the other frog diagrams so labeled are adequate. However, to those of us less informed it would be nice to have at least one frog skull fully labeled. The same comment could be made for some of the other illustrations, especially if the book is to be used in teaching situations.

The book is extremely useful both as a reference and as a teaching aid. It was something that the herpetological community needed, and I for one appreciate its availability. It includes such a diversity of material it is easy for a reviewer to find something to criticize.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

ANURA

ACRIS CREPITANS BLANCHARDI (Blanchard's Cricket Frog). USA: ARKANSAS: Stone Co: 18 km S of Junction with Ark. Rt. 14 on Ark. Rt. 5. 5-7 June 1970. F. Killebrew, H. Blair, D. Stout, J. Sikes, D. Bailey, and A. Clark. Verified by F. C. Killebrew. West Texas State University Museum of Natural History (WTSU 592, 596, 599, 601, 604, 605, 609, 611, 619, 628). New county record. Fills in gap between previous county records (Dowling, 1957, Occas. Papers University Ark. Mus. No. 3, 51 p.).

Submitted by **F. C. KILLEBREW,** Department of Biology, West Texas State University, Canyon, Texas 79016. ●

HYLA CINEREA (Green Treefrog). USA: ARKANSAS: Pike Co: Caddo River at Glenwood. 18 July 1973. J. Widmer, D. Goff, K. Conway, and J. Needham. Verified by F. C. Killebrew. West Texas State University Museum of Natural History (WTSU 1743-1746, 1758, 1759, 1766, 1767). New county record. Extends range 75 km N and 160 km W of nearest recorded localities in Hempstead and Jefferson Counties, respectively (Dowling, 1957, Occas. Papers University Ark. Mus. No. 3, 51 p.).

Submitted by **F. C. KILLEBREW,** Department of Biology, West Texas State University, Canyon, Texas 79016. ●

PSEUDACRIS TRISERIATA (Striped Chorus Frog). USA: ARKANSAS: Baxter Co: Ark. Rt. 5 at Moccasin Creek. 5 June 1970. F. Killebrew and J. Sikes. Verified by F. C. Killebrew. West Texas State University Museum of Natural History (WTSU 581, 582). New county record fills in gap in north central Arkansas between localities in Lawrence and Madison Counties. (Dowling, 1957, Occas. Papers University Ark. Mus. No. 3, 51 p.).

Submitted by **F. C. KILLEBREW,** Department of Biology, West Texas State University, Canyon, Texas 79016. ●

NEW DISTRIBUTIONAL RECORDS FOR SELECTED AMPHIBIANS AND REPTILES OF TEXAS

In the past decade, considerable data have been published on the geographic distribution of Texas amphibians and reptiles (see Raun and Gehlbach, 1972; Hambrick, 1975, 1976; Karges, 1978, 1979, 1981; Vance, 1980a, 1980b; and others). Here, we report new distributional information for 20 species of amphibians and reptiles from nine Texas counties. Specimens are exclusively new county records for the given counties and are deposited in the North Texas State University Herpetological Collection (NTSUHC). Specimens are assigned individual catalog numbers, nomenclature follows Collins, *et al.* (1978) and identification was verified by the authors. We thank Drs. L. C. Fitzpatrick and E. G. Zimmerman for allowing us access to the collection.

CAUDATA

Ambystoma tigrinum tigrinum (Eastern Tiger Salamander): RED RIVER Co. 3.2 km NW Manchester at Big Pine Creek. 3 May 1979. E. G. Zimmerman *et al.* NTSUHC A-44 through A-51.

Notophthalmus viridescens louisiensis (Central Newt): RED RIVER Co. 3.2 km NW Manchester at Big Pine Creek. J. R. Glidewell *et al.* 4 May 1979. NTSUHC A-14.

SALIENTIA

Scaphiopus holbrooki hurteri (Hurter's Spadefoot): RED RIVER Co. 3.2 km NW Manchester at Big Pine Creek. E. G. Zimmerman *et al.* 3 May 1979. A-7 through A-12.

Hyla squirella (Squirrel Treefrog): SABINE Co. 16.0 km SE Hemphill on TX 87 in Sabine National Forest. C. W. Kilpatrick. 26 June 1972. NTSUHC A-40, 41.

Rana catesbeiana (Bullfrog): WICHITA Co. 1.6 km NE Electra on US 287. B. J. Hart. 16 October 1971. NTSUHC A-39.

Gastrophryne olivacea (Great Plains Narrowmouth Toad): SABINE Co. 16.0 km SE Hemphill on TX 87 in Sabine National Forest. C. W. Kilpatrick. 26 June 1972. NTSUHC A-42.

TESTUDINES

Chelydra serpentina serpentina (Common Snapping Turtle): COLLIN Co. 1.6 km WSW Blue Ridge at Pilot Grove Creek on FM 545. B. Venables *et al.* 31 July 1976. NTSUHC R-964. 6.8 km E Frisco at West Rowlett Creek on FM 720. J. R. Glidewell *et al.* 20 September 1976. NTSUHC R-998. FANNIN Co. 2.4 km SW Leonard on TX 78. J. R. Glidewell *et al.* 19 July 1976. NTSUHC R-997. RED RIVER Co. 3.2 km NW Manchester at Big Pine Creek. J. R. Glidewell *et al.* 8 September 1979. NTSUHC R-1087.

Sternotherus odoratus (Stinkpot): CAMP Co. 11.2 km SW Pittsburg at Ferndale Lake. P. J. Prete. 5 April 1979. NTSUHC R-1038, 1039. RED RIVER Co. 3.2 km NW Manchester at Big Pine Creek. J. R. Glidewell. 29 August 1979. NTSUHC R-1075 through R-1080.

Chrysemys concinna texana (Texas River Cooter): CAMP Co. 11.2 km SW Pittsburg at Ferndale Lake. P. J. Prete. 5 April 1979. NTSUHC R-1041, 1042. DENTON Co. 6.4 km S Denton on US 377 at Brush Creek. D. Orf. 15 June 1976. NTSUHC R-1000.

Chrysemys scripta elegans (Red-eared slider): CAMP Co. 11.2 km SW Pittsburg at Ferndale Lake. P. J. Prete. 5 April 1979. NTSUHC R-1040. COLLIN Co. 5.6 km N Blue Ridge on TX 78. J. R. Glidewell. 19 July 1976. NTSUHC R-984. 8.0 km ENE Blue Ridge on FM 981. J. Hughes *et al.* 13 July 1976. NTSUHC R-1015. 6.4 km N Farmersville on TX 78 at Indian Creek, J. R. Glidewell *et al.* 10 August 1976. NTSUHC R-1019 through R-1021. COOKE Co. 19.2 km NW Gainesville on FM 1201 at H. H. Moss Lake. J. R. Glidewell *et al.* Various dates from 8 April 1977 through 21 May 1980. NTSUHC R-710 through R-962. These 252 *C. s. elegans* represent voucher specimens for Glidewell's Ph.D. Dissertation (In preparation). Also, they partially fill the hiatus in a four county area of extreme northcentral Texas.

Graptemys kohni (Mississippi Map Turtle): CAMP Co. 11.2 km SW Pittsburg at Ferndale Lake. P. J. Prete *et al.* 4 June 1979. NTSUHC R-1095. The complete distribution of *G. kohni* in Texas is taxonomically confusing (see Raun and Gehlbach, 1972).

Terrapene carolina triunguis (Three-toed Box Turtle): RED RIVER Co. 3.2 km NW Manchester at Big Pine Creek. J. R. Glidewell and J. Hughes. 4 May 1979. NTSUHC R-1052, 1110. 8.0 km NE Clarksville on FM 1159. R. Meckel. 5 July 1980. NTSUHC R-1090.

Trionyx spiniferus pallidus (Pallid Spiny Softshell): COOKE Co. 19.2 km NW Gainesville on FM 1201 at H. H. Moss Lake. J. R. Glidewell. 8 July 1976. NTSUHC R-1096, 1097.

SERPENTES

Coluber constrictor flaviventris (Eastern Yellowbelly Racer): COLLIN Co. 4.8 km NNE Westminster on TX 121 near county line. J. R. Glidewell and J. Hughes. 15 July 1976. NTSUHC R-985.

Elaphe guttata emoryi (Great Plains Rat Snake): DENTON Co. 0.5 km W Sanger at junction FM 455 & I-35. P. Grant. 15 May 1978. NTSUHC R-1064.

Elaphe obsoleta lindheimeri (Texas Rat Snake): CASS Co. 4.8 km E Atlanta on FM 249. L. Burrows. 23 August 1970. NTSUHC R-706.

Lampropeltis getulus holbrooki (Speckled Kingsnake): CASS Co. 9.6 km N Queen City on US 59. L. Burrows. 24 August 1970. NTSUHC R-707. 4.8 km E Atlanta on FM 249. L. Burrows. 17 August 1970. NTSUHC R-708. COOKE Co. 12.8 km NW Gainesville on FM 1201. J. R. Glidewell. 17 June 1977. NTSUHC R-1023.

Masticophis flagellum flagellum (Eastern Coachwhip): COLLIN Co. 8.0 km WSW Princeton on US 380. G. S. Hacker. 8 May 1977. NTSUHC R-966, 977.

Opheodrys aestivus (Rough Green Snake): COLLIN Co. 3.2 km NE Westminster on FM 455. J. R. Glidewell and J. Hughes. 15 July 1976. NTSUHC R-994.

Storeria dekayi texana (Texas Brown Snake): RED RIVER Co. 3.2 km NW Manchester at Big Pine Creek. J. R. Glidewell. 7 September 1979. NTSUHC R-1088.

OPHISAURUS VENTRALIS (Linnaeus): AN ADDITION TO THE LIZARD FAUNA OF VIRGINIA

Prior to McConkey's (1954) revision of North American *Ophisaurus*, checklists and other publications (Dunn, 1918; Brumfield, 1937; Carroll, 1950; Werler and McCallion, 1951) listed *O. ventralis* as a member of Virginia's fauna. McConkey's (1954) notation that only *O. attenuatus longicaudus* occurred in Virginia led to some confusion and speculation on its occurrence. The species was included in some subsequent checklists (Schmidt, 1953; Burger, 1958; Delzell, 1979) and omitted in others (Anon., 1976; Mitchell, 1977). This problem is clarified with the collection by us of an adult male *O. ventralis* (USNM 221849) 13.3 km S Sandbridge (USGS marker in Sand Bridge) in False Cape State Park, Virginia Beach, Virginia, on 16 May 1981. It was collected DOR on a sandy road adjacent to Spratt's Cove, a marsh-lined cove leading to Back Bay. The specimen agrees in every respect with other specimens of *O. ventalis* as described by McConkey (1954), Conant (1975), and Martof, *et al.* (1980). This record confirms the presence of *O. ventralis* in Virginia and extends the known range 67 km NNW of the previous northernmost locality, 1.4 km S Wright Memorial Monument, Bodie Island, Dare County, North Carolina (W. M. Palmer, pers. comm.; Brothers, 1965).

ACKNOWLEDGMENTS

Permission to collect in Virginia State Parks was granted through Collection Permit 010281 to J. C. Mitchell and C. A. Pague.

HERPETOLOGICAL RECORDS FROM NORTHWESTERN ARIZONA

During the year 1981, the Bureau of Land Management, Department of the Interior, Phoenix District, Kingman Resource Area, conducted a herpetological inventory in the area north of Kingman. Listed below are records that have been determined to be range extensions. Voucher specimens are currently on file at the Bureau of Land Management, Kingman Resource Area, 2475 Beverly Avenue, Kingman, Arizona, 86401. Vegetative associations listed are based on Brown and Lowe (1974).

SAURIA

Cnemidophorus velox - Mohave County, Arizona, ca 5,600 ft. Music Mountains, 1.6 km NE Hells Canyon, 69 km NNE Kingman, T28N, R16W, SE, Sec. 36, Great Basin Conifer Woodland, 28 April 1981 (BLM 8100). Additional records by legal: T28N, R15W, SW, Sec. 30, T28N, R16W, NE, Sec. 24; T28N, R15W, NE, Sec. 31; T28N, R15W, SW, Sec. 19, Great Basin Conifer Woodland. Extends range 40 km west of that illustrated by Stebbins (1966).

Cnemidophorus exsanguis - Mohave County, Arizona, ca 4,500 ft. Cerbat Mountains, 5.1 km N Kingman, T24N, R18W, SE, Sec 16, Great Basin Conifer Woodland, 27 May 1981 (BLM 8275). Additional records by legal: T24N, R18W, SE, Sec. 15; T24N, R18W, NW, Sec. 23, Great Basin Conifer Woodland. Extends range 55 km NNW of that reported by Jones *et al.* (1981).

Eumeces gilberti arizonensis - Mohave County, Arizona, ca 4,800 ft. Cerbat Mountains, 20 km NNW Kingman, T24N, R18W, SE, Sec. 15, Great Basin Conifer Woodland, 11 April 1981 (BLM 8014). Additional records by legal: T24N, R18W, NW, Sec. 23, T24N, T18W, NE, Sec. 20, Closed Chaparral and Juniper-Oak extends range 43 km NNW of that reported by Jones *et al.* (1981); -Mohave County, Arizona, ca 5,500 ft., Music Mountains, 67 km NNE Kingman, T28N, R15W, NW, Sec. 31, Great Basin Conifer Woodland, 10 May 1981 (BLM 8197). Extends range 74 km N of that reported by Jones *et al.* (1981); - Mohave County, Arizona, ca 2,900 ft. Black Mountains, 27 km SW Kingman, T19N, R19W, NW, Sec. 4, Mohave Desert Scrub, 15 April 1981 (BLM 8030, 8031, 8032, 8033, 8035, 8036, 8037). Extends range 32 km WSW of that reported by Jones *et al.* (1981).

Phrynosoma douglassi - Mohave County, Arizona, ca 4,500 ft. Cerbat Mountains, 20 km NNW Kingman, T24N, R18W, SE, Sec. 16, Great Basin Conifer Woodland, 15 April 1981 (BLM 8014). Additional records by legal: T24N, R18W, NW, Sec. 23, T24N, T18W, NE, Sec. 23, Interior Chaparral, Extends range 55 km NNW of Hualapai area illustrated by Stebbins (1966); - Mohave County, Arizona, ca 5,500 ft. Music Mountains, 67 km NNW Kingman, T28N, R15W, SW, Sec. 30, Great Basin Conifer Woodland, 10 April 1981 (BLM 8011, 8047). Additional records by legal: T28N, R15W, NW, Sec. 31; T28N, R16W, NE, Sec. 24, Interior Chaparral. Extends range 55 km W of that illustrated by Stebbins (1966).

SERPENTES

Tantilla planiceps atriceps - Mohave County, Arizona, ca 4,200 ft. Cerbat Mountains, 5.1 km N Kingman, T24N, R18W, NE, Sec. 20, Interior Chaparral, 15 April 1981 (BLM 8038). Additional records by legal: T24N, R18W, SE, Sec. 16, T24N, R18W, SE, Sec. 15, Great Basin Conifer Woodland. Extends range 51 km of that reported by Jones *et al.* (1981).

Leptotyphlops humilis - Mohave County, Arizona, ca 3,300 ft. Hells Canyon, 30 km N Kingham, T27N, R16W, SE, Sec. 4, Mohave Desert Scrub, 8 June 1981 (BLM 8329). Extends range 67 km E Colorado River as reported by Hahn (1979).

Thamnophis cyrtopsis - Mohave County, Arizona, ca 7,000 ft. Hualapai Mountains, 18 km SE Kingman, T20N, R15W, SW, Sec. 32, Wild Cow Spring, Interior Chaparral, 14 July 1981 (BLM 8358). Extends range 13 km to the NW as reported by Jones *et al.* (1981).

DISTRIBUTIONAL RECORDS FOR CENTRAL AND SOUTHERN TEXAS

The following new county records supplement the compendium of Raun and Gehlbach (1972, Dallas Mus. Nat. Hist. Bull. 2). Unless otherwise indicated, specimens were collected by one or both of the authors; all identifications have been verified by Lieb. Collected materials are deposited in the following biological resource collections: Natural History Museum of Los Angeles County (LACM), Texas Cooperative Wildlife Collection (TCWC), California State University at Dominguez-Hills (CSDH), Amphibian and Reptile Osteological Collection, University of Southern California (JMS), and Laboratory for Environmental Biology (UTEP).

ANURA

Acris crepitans (Northern Cricket Frog). GUADALUPE Co. 7.5 km NNE Kingsbury. 18 April 1976. LACM 125398.

Bufo debilis (Green Toad). MCMULLEN Co. 25 km S Tilden, 1-2 km (by RnRd 1962) E StHy 16. 28 August 1969. LACM 128603.

Bufo speciosus (Texas Toad). FRIO Co. 24 km SE Pearsall. AOR RnRd 1582, 25 July 1975. UTEP OC-920.

Siren intermedia IN MEXICO

Siren intermedia has been reported from only two localities in Mexico: Matamoros, and 30 miles south of Matamoros, in extreme northeastern Tamaulipas (Goin, 1942, 1957). Discovery of the species at yet another location somewhat further to the south is therefore of interest.

The new locality is 62 miles SSW of the International Bridge, Matamoros, and 9.5 miles north of E. Tejon, on Route 101, Tamaulipas. The site consists of a pond some 1 to 4 feet deep, and thick with aquatic weeds, particularly *Chara*. Dominant vegetation in the immediate vicinity is mesquite, with some *Opuntia* and *Acacia*. Specimens were collected by seine on three occasions: two specimens by J. Mecham and J. Bogart on 22 June 1965, 1 specimen by Mecham, R. Mitchell, and K. Johnson on 23 January 1966, and 2 specimens by Mitchell, F. Abernathy, W. Rhodes, and V. Colvin on 26 August 1966. One specimen has been placed in the collection of the Texas Tech University Museum.

A number of mature *Notophthalmus meridionalis* were collected in the pond on the June and August dates. None were found in January.

Two new records of the bog turtle, *Clemmys muhlenbergi* Schoepff, in Georgia

Clemmys muhlenbergi is a secretive species with a spotty distribution, ranging from upper New York and eastern New Jersey southward into the southern Appalachians in Georgia.

The bog turtle was first recorded in Georgia by Hale and Harris (1980. Geographical distribution: *Clemmys muhlenbergi*. SSAR Herp. Review 11(1):1.) from Union County. Five specimens were collected during a nine week period from May to July. This site is a woodland bog with a canopy of yellow poplar (*Liriodendron tulipifera*) (P. E. Hale, Univ. Ga., pers. comm.). An adult female bog turtle was found at this site in July 1981 after five unsuccessful visits (Ben Sanders, U.S. Forest Ser., pers. comm.).

Two adult female bog turtles were found at two Georgia localities on 8 August 1980 by Carl E. Putnam, Jr. The first was found basking on a clump of sphagnum moss at 0930 hr in a bog 3.2 km N Dillard, Rabun County. The air temperature was 23° C. The second turtle was found at 1040 hr in a bog next to Rabun Bald Rd., 3.5 km S Scaly (N.C.), Rabun County. The air temperature was 24° C. Neither turtle was measured, although both were adults; age was indiscernable due to smoothly worn shells. The second turtle had algae growing on the carapace.

Both sites are sphagnaceous bogs with sphagnum mosses *(Sphagnum ssp.)* and alders *(Alnus ssp.)* the predominant growth. The pitcher plant *(Sarracenia purpurea)* reaches its southern-most limit in the Scaly bog (Steve Bowling, Ga. Bot. Soc., pers. comm.).

These two records extend the range, in Georgia, at least 60 km NE of the Union County locality. The range is also extended by at least 10 km S from the known localities in bordering Macon County, North Carolina (Nemuras, K. 1974. Wildl. North Carolina, 38(2):13-15).

These animals were deposited in the vertebrate collection of the University of Georgia Museum of Natural History (UGA-MNH 15021 and 15022). This field work was funded with research grants from the Education, Research, and Conservation Committee of the Zoological Society of Atlanta.

Origin of *Rana catesbeiana* Populations in the Rio Grande Delta of Texas

The bullfrog, *Rana catesbeiana,* occurs over much of the eastern United States (Conant, 1975). Large-scale introductions have increased the geographic range so that the original natural limits are confused. In Texas, *R. catesbeiana* naturally occurred over the eastern one-third of the state. Raun and Gehlbach (1972:10) believed the southwestern edge of native occurrence to be on the Coastal Plain in the vicinity of the lower Nueces River. Recently, Neck (1981) reported on the observations of an early Mexican expedition which described a frog "as large as the head of a man . . . where astounding call resembles the bellowing of a bull" in Webb County, well inland on the upper Coastal Plain in 1828.

Raun and Gehlbach (1972:Map 35) reported no bullfrog populations in the lower Rio Grande Valley of Texas (Rio Grande delta). More recently, Karges (1978) reported bullfrogs collected in 1977 on Texas Route 186 approximately 20.6 km west of Raymondville, Willacy County. A local informant (J. Ideker, pers. comm.) reported that residents believe these frogs originated from a local frog farm. No further information has been available as to the origin of this population.

The probable origin of this population was revealed in *Monty's Monthly,* a development-oriented publication which was issued from 1919 to 1939. A report (Anonymous, 1927), assumed to be written by P. E. "Monty" Montgomery, editor of the periodical stated, that Judge D. F. Strickland of Mission possessed a frog farm located "out northwest of Pharr" (Hidalgo County). The farm consisted of a lake fed by irrigation water lifted from the Rio Grande. The lake was also stocked with "bass and crappie," but was equipped with "a system of strainers to keep out undesirables . . . . such as gars, terrapins, etc." The lake banks were said to "resound with the orchestral strains of bullfrog music which would make a Louisianian or Mississipian homesick from hearing the dulcet tones." The frog farm was only for use by family and friends; apparently no commercial development was planned by Strickland.

The same article alludes to the former existence of another frog farm in the delta area. This venture, by Nat Wetzel at Raymondville, Willacy County (northeast of Pharr), failed because the "frog pond was of such diminutive dimensions that his imported stock of 'greenbacks' abruptly left enmasse one night." The bullfrogs at the Strickland pond, on the other hand, were described as being "perfectly at home" and "increasing in geometrical proportion."

The bullfrog's requirement for permanent water restricts distribution of this species in the Rio Grande delta area. The collection site of Karges (1978) is an area with several drainage ditches, but is within 9 kilometers of Monte Alto Reservoir, the largest reservoir in the delta area. Smaller lakes are located less than 5 kilometers from the site. Evidence at hand now indicates that descendants of these populations still exist in the area. Field investigators in the area should consider the bullfrog as a possible localized species around other similar reservoirs in this region.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

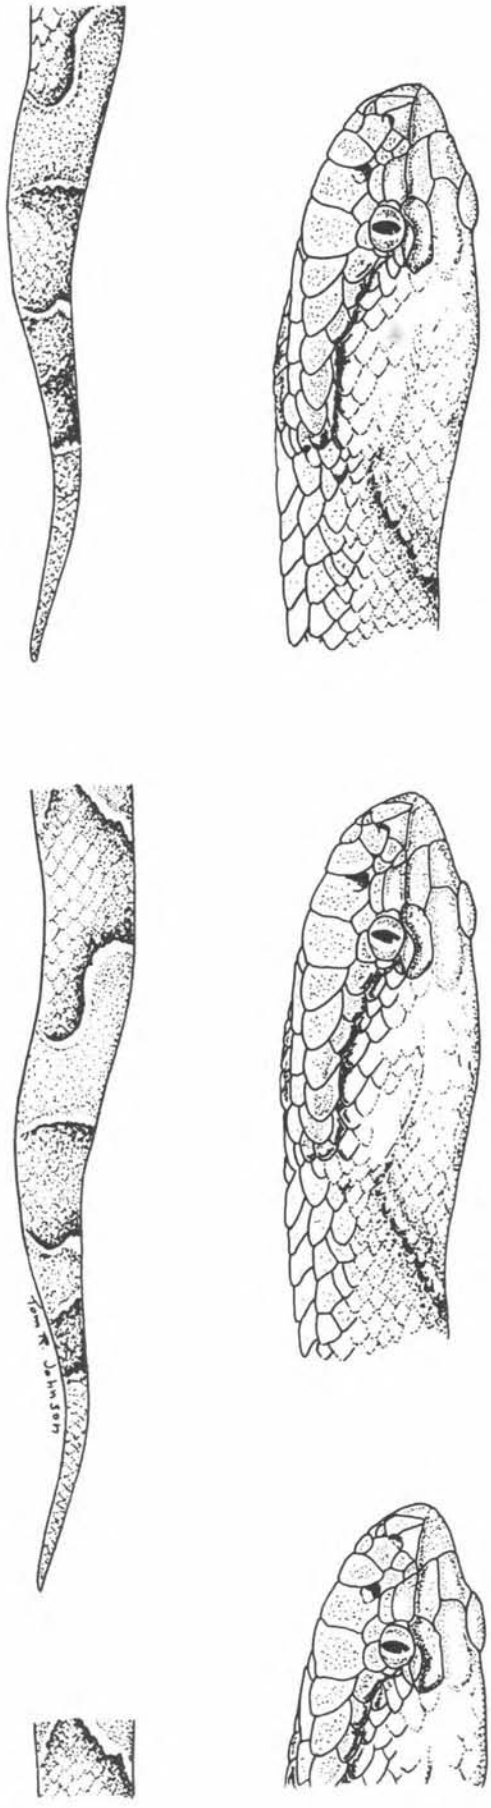
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1983

(Please send only U.S. funds on U.S. banks; make checks payable to SSAR)

Student member	$15.00
Regular member	$18.00
Sustaining member	$30.00
Contributing member	$50.00
Institutional	$30.00



Non-U.S. members and institutions must also include $5.00 additional for postage.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Henri C. Seibert

JOINT MEETING
The 26th Annual Meeting of
THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
with
The 31st Meeting of
THE HERPETOLOGISTS' LEAGUE
at
THE UNIVERSITY OF UTAH
Salt Lake City, Utah
7-12 August 1983

The University of Utah campus in spring. The Wasatch Mountains are in the background.

SYMPOSIUM

Biogeography of the Herpetofauna of Mexico: Perspectives and Approaches. In honor of Hobart M. and Rosella B. Smith.

DISTINGUISHED HERPETOLOGIST

Roger Conant

PREREGISTRATION AND ABSTRACTS

The final call for papers and preregistration forms will be mailed to all members of both societies in March 1983. Deadline for the receipt of titles and abstracts is 1 May 1983 —this will be rigidly enforced. Foreign scientists who plan to attend and present papers are encouraged to indicate this intention and submit abstracts *far* in advance. Any interested non-member may request the premeeting booklet.

PROGRAM SUMMARY

Sunday, 7 August
- Registration at Austin Hall
- Board & Trustees Meetings
- SSAR Regional Herpetological Societies — Social

Monday, 8 August
- HL Distinguished Herpetologists' Lecture by Roger Conant
- SSAR/HL Liaison Committee
- SSAR Regional Herpetological Societies — Paper Session
- Social and Auction

Tuesday, 9 August
- Group Photo
- Social — Outdoor Barbecue

Wednesday, 10 August
- Business meetings
- Herpetological Resources Committee
- Social — Snowbird Ski Resort

Thursday, 11 August
- Open Discussion of Papers
- SSAR Board Luncheon
- Field Trips
- Open House, Research Facilities

Registration at Union: Daily
Symposium: Tuesday and Wednesday
Paper Sessions: Monday-Thursday
Poster Sessions: Monday-Thursday
Exhibits (art, live, commercial): Monday-Wednesday

MEETING SITE

The University of Utah is in Salt Lake City and is regarded as a major educational, cultural, and medical center in the Intermountain West. The University is a community of 33,000 on an attractive campus of 1500 acres with 149 buildings. The campus sits at 5,000 ft. on a Pleistocene bench (a former shoreline of Lake Bonneville) at the base of the Wasatch Mountains. From campus there is a panoramic view of Salt Lake Valley, the Great Salt Lake and its islands, and the Oquirrh Mountains to the West.

All meeting sessions will be centralized in the air conditioned University of Utah Union Building. Weather in August is usually comprised of hot, dry days and cool nights. A sweater or jacket is wise for any outdoor function after dark.

HERPETOLOGY IN UTAH

The University of Utah, Salt Lake City
- Dennis M. Bramble — Biomechanics of feeding and locomotor systems
- Orlando Cuellar — Parthenogenesis; reproductive cycles
- Harold F. Hirth — Biology of marine turtles
- John M. Legler — Chelonian biology

Veterans Administration Hospital, Salt Lake City
- Jim Glenn — Venomous snakes

Utah State University, Logan

ACCOMMODATIONS

Residence Halls. Air conditioned rooms in Austin Hall near Union; $10 single and $17 double (soap, towels, linen, and blankets included). Shared toilet facilities for each block of rooms. Snack kitchen and refrigerator on each floor. An abundance of indoor and outdoor lounging facilities.

Motels/Hotels. Blocks of rooms at reduced rates have been reserved at hotels and motels at varying distances from campus. Write to chairman for information.

Camping. A few recreational vehicle sites with full hookups available on campus; many sites for self contained units. Commercial campgrounds (KOA, *etc.*) within 3 miles; Forest Service Campgrounds within 10-15 miles.

MEALS

A full range of eating facilities is available within the Union, at Ballif Hall, and the University Hospital. All facilities accept cash.

FACILITIES

A complete range of recreational-athletic facilities is available for $3.00. Rental of camping-backpacking gear can be arranged.

ALCOHOL

No problem. The liquor laws in Utah are unusual but not difficult.

ACTIVITIES AND TOURS

A variety of activities and tours will be planned for spouses and families. These will concentrate on the local Mormon scene and the mountain-desert spectrum and its recreational potential. Information will be available for any person or family wishing to do these things independently. Field trips will be announced.

TRANSPORTATION

Make air reservations to Salt Lake City International Airport. There are two adjacent terminals. Information for arriving attendees will be posted prominently. Transportation to Austin Hall is $.50 by city bus, $8.50-$10.00 by taxi. A shuttle will be arranged to maximize transportation opportunities. Attendees arriving by automobile should enter the campus from the East (on Wasatch Drive) and look for the entrance to Austin Hall (opposite hospital and fire station). Campus parking permits are necessary.

MEETING CHAIRMAN

John M. Legler, Department of Biology, University of Utah, Salt Lake City, Utah 84112
Telephone 801-581-6609 ●

JOINT MEETING
The 26th Annual Meeting of
THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
with
The 31st Meeting of
THE HERPETOLOGISTS' LEAGUE
at
THE UNIVERSITY OF UTAH
Salt Lake City, Utah
7-12 August 1983

FIRST CALL FOR PAPERS

Please return completed form and abstract by 1 May 1983 to: John M. Legler, Department of Biology, University of Utah, Salt Lake City, UT 84112.

Please type the following:

Author(s) (last names first); **underline** speaker: _____

_____

Institution(s): _____

_____

Speaker's address: _____

_____ Phone: _____

Speakers will be notified of the time and date of presentation after 1 May 1983.

Check the appropriate item: **[NOTE: ALL PAPERS REQUIRE ABSTRACTS]**

_____Contributed paper

_____Student paper (for HL prize; authored and presented by students *only*)

_____Poster session (HL will present a prize for best poster presentation)

_____Presentation by title only (requires abstract)

All presented papers are allotted 15 minutes (*including* discussion)

A 35 mm carousel slide projector, screen, pointer, PA system, and illuminated lectern will be available to all speakers. You must request *any other equipment* needed in this space: _____

_____.

ABSTRACTS

Directions. Use new ribbon and elite type (*i.e.*, 12 characters per inch). Avoid old mechanical typewriters and microdot printers. Underline scientific names only. Your abstract will appear exactly as you submit it except for possible reduction; please take care. *DO NOT EXCEED THE SPACE IN THE BOX* (approximately 200 words). First line, names of authors. Second line, addresses of authors. Third line, title. Fourth line begin abstract. **SEE SAMPLE.**

SAMPLE ABSTRACT

Legler, J.M., and R.M. Winokur

VASCULAR BUCCAL FIMBRIAE IN *CARETTOCHELYS INSCULPTA* (CRYPTODIRA: CARETTOCHELYIDAE).

Recent ecological studies of *Carettochelys insculpta* in Northwestern Australia have revealed several morphological structures that are unknown or poorly known. One of these is . . .

ABSTRACT FORM

WORLD CONGRESS OF HERPETOLOGY

By recent action of the officers and official representatives of the major national and international herpetological societies, an international committee has been established to plan the first World Congress of Herpetology. The congress will be held in 3-5 years at a site yet to be selected. The Planning Committee consists of:

Donald G. Broadley (Zimbabwe)
Harold G. Cogger (Australia)
J. C. Daniel (India)
Ilya S. Darevsky (U.S.S.R.)
Marinus S. Hoogmoed (Netherlands)
Toshijiro Kawamura (Japan)
Michael R. K. Lambert (U.K.)
Hubert Saint Girons (France)
P. E. Vanzolini (Brazil)
David B. Wake (U.S.A.)
Kraig Adler (U.S.A.), *Secretary-General*

The congress will be organized to include a wide range of topics, to appeal to all persons interested in the scientific study of amphibians and reptiles. The committee currently is setting guidelines for operation, including the establishment of a larger and broadly representative International Herpetological Committee to provide a self-perpetuating mechanism for future congresses.

The Planning Committee solicits comments from the herpetological community on all aspects, in particular the choice of a convenient site and content of the congress. Potential hosts for the congress are also invited to communicate. Further announcements will be published in this journal.

Address comments or questions to any member of the Planning Committee or to the Secretary-General: Professor Kraig Adler, Cornell University, Section of Neurobiology and Behavior, Seeley G. Mudd Hall, Ithaca, New York 14853, U.S.A.

SSAR BUSINESS

BALLOTS FOR NON-U.S. MEMBERS: AN APOLOGY

SSAR is an international society and, as such, all members have a right to participate in society affairs, especially in the election of officers. In past years ballots were put inside *Herpetological Review* but since *HR* was sent by surface mail the ballots often were not received by overseas colleagues until after the election deadline. Last August the Board of Directors decided to send ballots separately to non-U.S. members by airmail, even at considerable additional cost, in order to permit them to vote. Unfortunately, due to an error made by the mailing house which handles *HR*, these separately-mailed ballots were sent by surface post. The Society apologizes for this error, which will be corrected for next Fall's election. Through the efforts of GRP and our printer, Steve Meseraull, SSAR will be reimbursed by the mailing house for all printing and postage costs associated with these ballots. ●

CURRENT LITERATURE TO BE A SEPARATE SERIES

The 31 May 1965 issue of *The Ohio Herpetological Society Newsletter* contained two pages of herpetological titles. That unpretentious effort marked the beginning of SSAR's long-standing commitment to providing a titles service to the membership. Over the intervening years, this service grew and experienced the inevitable ups and downs attendant to so arduous an undertaking. The general trend was upward, with the efforts of many volunteers combining to advance it. In June of this year, SSAR members will receive (as part of their member benefits) Number 1 of a new series entitled *Current Herpetological Literature.* The new series, printed by Allen Press, Inc. and coordinated with the *Journal of Herpetology*, will hold titles maintained on magnetic tape and coded with key words so that each number may be indexed, rather than having all titles listed simply alphabetically. The new series will be edited by George R. Pisani, with Joseph Dinardo as Associate Editor. The initial number will also contain a complete history of SSAR's titles service in recognition of all who have contributed to this effort.

The editors will prepare titles contributed by volunteers so that data entry may be via optical character reader, a much more efficient method than we've used before. Said editors urgently need the help of volunteer searchers (in this country and others) to scan journals for herpetological titles. We would like to establish a standing panel of scanners (which would be listed in each number) to assure accuracy and uniformity. The key to providing this service to our membership at no added cost is the same key to every other society function — the dedication of members to service. Volunteers will not be "worked to the bone." So, I ask that those of you with access to extensive libraries and any non-USA periodicals and books contact the editor and, ideally, send me a list of what serials are available to you which may carry herpetological articles. We do not need scanners for any serials published by Allen Press, Inc. since these can be sorted automatically at Allen Press. I also ask that the editors or recipients of certain serials (state journals, university and zoo publications, regional society publications, museum series) participate by volunteering to send us titles of herpetological articles published therein.

The value of this effort hinges on the thoroughness with which we can cover the literature, and that requires considerable help. Preparing and publishing the data will take a large portion of the time Joe and I can devote to this service, so please volunteer.

GEORGE R. PISANI
Division of Biological Sciences
The University of Kansas
Lawrence, KS 66045 ●

PROPOSED AMENDMENTS TO SSAR BYLAWS

Members of the Society for the Study of Amphibians and Reptiles are hereby notified of a proposal approved by the SSAR Board of Directors to amend the following articles of the SSAR Bylaws (1970. *J. Herpetology* 4:95-98) in order to make the Publications Secretary a voting member of the Board:

Article II, Section 3 (p. 96) currently reads:

"The terms of office for the President, President-elect, Immediate Past-President, Secretary and Treasurer shall be for one year; those for the directors shall be for three years (with election to provide for staggered terms so that no more than two Directors shall be elected in any one year)."

If amended, it will read:

"The terms of office for the President, President-elect, Secretary, Treasurer, Publications Secretary and Immediate Past-President shall be for one year; those for Directors shall be for three years (with election to provide for staggered terms so that no more than two Directors shall

be elected in any one year)."

Article II, Section 6d (p. 97) currently reads:
"The Publications Secretary shall assist in the storage, maintenance of inventories and dissemination of the publications of the Society, in particular back issues of the Journal. He shall report annually to the Treasurer."

If amended, it will read:
"The Publications Secretary shall assist in the storage, maintenance of inventories and dissemination of the publications of the Society. He shall serve as an appointive member of the Board of Directors."

Article III, Section 1 (p. 98) currently reads:
"The Board of Directors shall consist of the President, President-elect, Secretary, Treasurer, six Directors and the immediate Past-President."

If amended, it will read:
"The Board of Directors shall consist of the President, President-elect, Secretary, Treasurer, six Directors, Publications Secretary and Immediate Past-President."

These proposed amendments will be on the agenda for discussion at the 1983 general business meeting in Salt Lake City, Utah, during 7-12 August 1983. A ballot will be submitted by mail to the SSAR membership after the annual meeting in Salt Lake City.

Respectfully submitted,
James S. Jacob
SSAR Secretary ●

SSAR ELECTION RESULTS

The results of the 1982 SSAR Election are as follows:

President-Elect: Carl Gans
Secretary: James Jacob
Treasurer: Henri Seibert
Board-Zoo: Hugh Quinn
Board-Regular: Linda Maxson

The Society extends its gratitude to the Nominating Committee (John Wright, Chair) for its hard work and the excellent slate of candidates. ●

Pritchard & Trebbau's TURTLES OF VENEZUELA

Due to unavoidable delays in production, publication of this book will be delayed by several months. Since we do not expect it to be issued until fall 1983, the special prepublication prices announced in the December 1982 issue of *Herpetological Review* will be extended until 1 September 1983. The Society regrets this inconvenience. ●

To Be Published June 1983

Silver Anniversary Year 1958- 1982 Membership Directory Of The Society For The Study Of Amphibians And Reptiles

The first comprehensive listing of the membership of the society now numbering over 2,000 professional and amateur herpetologists. This directory will also include a brief history of the society, the constitution and bylaws, a listing of all previous society officers and annual meeting sites, and a listing of worldwide herpetological societies and organisations and their publications prepared by the 1982 Regional Society Liaison Committee.

TO ORDER:

To SSAR members, *if ordered before 1 August 1983*..... ☐ $2

To non-members; Institutions; all orders after 1 August.... ☐ $4

The directory will be in the same style and size as the *Journal of Herpetology* for easy binding. Commercial use of the list will not be permitted. Prices include packing and shipping. Address orders to Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056 U.S.A. Receipt sent on request only. Mark here ☐ if you wish to have a complete pricelist of SSAR publications including the *Journal of Herpetology*, *Facsimile Reprints in Herpetology*, *Herpetological Review*, *Herpetological Review*, *Herpetological Circulars*, *Catalogue of American Amphibians and Reptiles*, and the publications of The Ohio Herpetological Society.

PRIZE FOR BEST STUDENT JOURNAL PAPER

An annual prize of $100 was established in 1973 to be awarded to that student publishing the most significant paper in the *Journal of Herpetology* during the preceding year. This award is to serve a dual purpose: (i) to recognize the important, original contributions made to our knowledge of amphibian and reptile biology by young persons; and (ii) to encourage students to publish in *Journal of Herpetology*. Unlike awards for oral presentations, which require the presence of the person at a particular meeting site in order to compete, this prize is open to all students throughout the world and thus is more fitting for a society having an international focus.

COMMITTEE

1. An *ad hoc* Prize Committee of five persons will be appointed by the Society Chairman early each year.

2. The Committee should be international in composition. Since Committee members will need to have the relevant *Journal* issues at hand, this should be noted in appointing non-American members.

ELIGIBILITY

1. A person must have been a student at an accredited school (elementary, secondary or university level) within one year of submitting the manuscript for publication. Submission dates can be verified by the Editor of the *Journal*.

2. The Committee Chairman should designate all articles to be considered. This list should be all-inclusive, even including those articles where author eligibility is possibly in doubt. After the vote, the highest-ranking, eligible person can be identified.

CRITERIA

1. The prize should be awarded to that person reporting the most significant new contribution to our knowledge of amphibian or reptile biology, interpreted in its broadest sense.

2. If the Committee so chooses, "no winner" may be declared.

AWARD

1. The Committee's decision should be reported to the Society's Chairman and Treasurer by June 1.

2. The Society Chairman will notify the awardee as soon as possible.

3. The award will be presented at that summer's Annual Meeting; it is hoped that the student will be present to accept the award. ●

MEETINGS

CALL FOR PAPERS

All herpetologists are invited to submit for consideration the titles of papers they wish to present at the 7th Reptile Symposium on Captive Propagation and Husbandry to be held at Dallas, Texas. Paper lengths may range from 15 to 40 minutes. A preliminary program will be established by May, 1983, so a 100-150 word abstract of a presentation should be submitted by contributors prior to 1 May 1983. *Titles should be submitted as soon as possible.* Final manuscripts should be submitted prior to 1 June 1983.

Submit all program information to: Dr. Peter J. Tolson, Program Chairman, Toledo Zoological Society, 2700 Broadway, Toledo, OH 43609; 419/385-5721. Symposium Series Director is: Richard A. Hahn, Zoological Consortium, Inc., 13019 Catoctin Furnace Road, Thurmont, MD 21788; 301/662-0328. Symposium Coordinator is: Mike Goode, Columbus Zoo, 9990 Riverside Drive, Powell, OH 43065; 614/889-9472, 889-9475. Host Co-Chairmen are: William E. Lamoreaux and David G. Barker, Department of Herpetology, Dallas Zoo, 621 E. Clarendon Drive, Dallas, TX 75203; 214/946-6898. European Liaison is: Quentin Bloxam, Curator of Reptiles, Jersey Wildlife Preservation Trust, Channel Islands, Great Britain; 0534 61949. ●

CALL FOR PAPERS

The Chihuahuan Desert Research Institute and Sul Ross State University announce the second Chihuahuan Desert Symposium to be held in Alpine, Texas, October 20-21, 1983. Papers should pertain to the objectives of the Symposium:

To update knowledge of the Chihuahuan Desert Region.
To identify potential resources.
To address new concerns for the Region.
To discuss utilization of resources.
To identify changes within the Region.
To address the future outlook of the Region.

Abstracts must be sent to the appropriate Session Chairman by July 15, 1983. Session Chairmen will review all abstracts and assign time slots upon acceptance. Only a limited number of papers will be accepted for each session. All presented papers will be limited to 12 minutes. Papers will be reviewed and published as Occasional Papers by the Chihuahuan Desert Research Institute over a two year period. Editorial guidelines will be provided to authors upon acceptance.

Send abstracts to the appropriate Session Chairman prior to July 15, 1983:

Botanical Biology: A. Michael Powell, Department of Biology, Sul Ross State University, Alpine, TX 79832

Vertebrate Biology: David K. Schmidly, Department of Wildlife Science, Texas A&M University, College Station, TX 77840

Invertebrate Biology: Jim V. Richerson, Department of Biology, Sul Ross State University, Alpine, TX 79832

Plant Resources and Agriculture: Jimmy Tipton, Texas A&M Agricultural Research Center, Texas A&M Circle, El Paso, TX 79927

Archeology and Anthropology: Robert Mallouf, Texas Historical Commission, Box 12276, Austin, TX 78711

Parks and Recreation: Robert Ditton, Recreation and Parks Department, Texas A&M University, College Station, TX 77840

Utilization and Management of Ecological Resources: Roland Wauer, 7500 Axton Street, Springfield, VA 22161

Inquiries for additional topics may be sent to: Dennie Miller, Executive Director, CDRI, Box 1334, Alpine, TX 79830. ●

BRITISH HERPETOLOGICAL SOCIETY MEETINGS 1983

The meetings are held in the Lecture Theatre of the Linnean Society of London, Burlington House, Piccadilly, London W1 and start at 7:00 P.M., unless indicated otherwise. SSAR members passing through London are most welcome.

February 23rd. Dr. P.A. Arak (Department of Zoology, University of Cambridge): Female choice in natterjack toad *(Bufo calamita)* breeding behaviour.

March 22nd. Annual General Meeting followed by Mr. Lionel Kelleway (Department of Zoology, University of Swansea): Control of reproductive behaviour in the adder, *Vipera berus;* to include a 16 mm research film.

April 14th. Professor H.C. MacGregor, Mrs. M.A. Horner and Mr. S. Sims (Department of Zoology, University of Leicester): European crested newts and their chromosomes: a study in evolution, development and molecular biology. Organised by the Linnean Society of London; all, including BHS members, welcome. Meeting starts at 5:00 P.M. Tea served at 4:30 P.M. in the Library, where BHS Library books are housed. There will be an informal BHS gathering after the meeting at *ca.* 7:00 P.M. in The Chequers, 16 Duke Street, London SW1.

May 5th. Mr. Keith Lawrence, MRCVS: Human causal diseases in captive reptiles.

May 26-27th. Dr. M.W.J. Ferguson (Anatomy Department, Queen's University, Belfast), organiser: A joint two-day symposium with the Zoological Society of London on "Reptile Biology" in honour of Professor Angus Bellairs on the occasion of his retirement, in the Meeting Rooms, Zoological Society of Lon-

don, Regent's Park, NW1. Admission by ticket; full programme and application forms available from the Zoological Society by end of March 1983. Details to be announced in *BHS Bulletin*. A Symposium Volume will be published by Academic Press.

June 15th.* Amphibians and reptiles of the **New World.** A discussion on care and breeding with the Captive Breeding Committee.

July 13th. A visit to the London Zoo. A meeting organised by the Captive Breeding Committee during a Members' Evening of the Zoological Society of London. BHS members and guests should meet at the Fellows' Entrance in the Outer Circle of Regent's Park. If late, please tell the Gateman you are with Mr. S. Townson.

September 21st.* Amphibians and reptiles of the **Old World.** Details as for June 15th.

October 8th. A joint Saturday meeting with ASRA (Association for the Study of Reptilia and Amphibia) at the Cotswold Wildlife Park, Oxon. Details to be announced in *BHS Bulletin*.

November 22nd. Dr. A. Hailey (Zoology Department, University of Nottingham): Ecology of the viperine snake, *Natrix maura*.

*Members should bring live animals, preserved specimens and 35 mm colour slides for display and to illustrate discussions. ●

Symposium on THE STRUCTURE, DEVELOPMENT, AND EVOLUTION OF REPTILES in honour of PROFESSOR A. d'A. BELLAIRS on the occasion of his retirement

This symposium organised by Dr. M.W.J. Ferguson, Department of Anatomy, Queen's University, Belfast, will be held in the Meeting Rooms of the Zoological Society of London, Regent's Park, London, NW1 4RY
on
Thursday, 26th and Friday, 27th May, 1983

This symposium is open to Fellows of the Zoological Society of London, members of The Anatomical Society of Great Britain and Ireland, The British Herpetological Society and to any scientist interested in the subject of the symposium. Tickets (free) will be issued by the Administrative Assistant, Zoological Society of London and a printed programme with booking form for coffee, luncheon, etc. will be available in March 1983. The papers given at the symposium will be published as a Festschrift in honour of Professor A. d'A. Bellairs in the series "Symposia of the Zoological Society of London" by Academic Press (editor M.W.J. Ferguson).

THURSDAY, 26th MAY, 1983

9.00-9.15 M.W.J. FERGUSON — Introduction.

MORPHOLOGY

Chairman: PROFESSOR A.S. BREATHNACH

DEVELOPMENT

Chairman: PROFESSOR L. WOLPERT, FRS

MANAGEMENT OF NONGAME SPECIES AND ECOLOGICAL COMMUNITIES

A workshop on management of nongame wildlife as species and as integral components of ecological communities will be held at the University of Kentucky, Lexington, Kentucky on June 11-12, 1984. The workshop is being sponsored by the Department of Forestry, University of Kentucky, in cooperation with the Kentucky Department of Fish and Wildlife Resources, Kentucky Nature Preserves Commission, TVA Land-Between-the-Lakes, the Daniel Boone National Forest, and the Kentucky Nature Conservancy. Subject areas to be included are: 1) inventory, including listing criteria and computerized retrieval systems; 2) management of nongame species, communities, and people; 3) monitoring methods to determine management effectiveness; and current and future research.

Individuals who wish to present a paper in one of the above areas should submit a 250-word abstract by 15 October 1983 to:

Dr. William C. McComb
Department of Forestry
University of Kentucky
Lexington, Kentucky 40546-0073

Notification of acceptance will be made by 15 January 1984. Instructions to authors regarding format and deadlines for complete manuscripts will be provided at that time. A published proceedings of all accepted papers will follow the workshop. ●

SOCIETIES

SOCIETAS EUROPAEA HERPETOLOGICA

The Societas Europaea Herpetologica (SEH) was founded on September 11, 1979 in Bonn, W. Germany by 24 herpetologists from eight European Countries. The aim of SEH is to further scientific research and nature conservation in the field of herpetology. It tries to realize this by promoting organization of congresses, meetings, symposia and publishing the journal 'Amphibia-Reptilia' (published quarterly, 360 + 24 pages per year). The present membership stands at 353, from 38 countries.

Interested persons should contact:

Dr. Marinus S. Hoogmoed
Rijksmuseum van Natuurlijke Historie
Postbus 9517
NL-2300 RA Leiden
Netherlands ●

MISSISSIPPI HERPETOLOGICAL SOCIETY

One year ago the Mississippi Herpetological Society was founded at a meeting held in Jackson. It was decided at that time to remain purely a local entity for as long as it took to establish ourselves and see if we were going to make it. A year has passed and we feel that it is time to announce our existence to the herpetological community outside Mississippi.

The MHS was founded 26 June 1981. An emblem was chosen which depicts a state map and two herps endemic to Mississippi, the black pine snake and the ringed saw-back turtle. At present our membership stands at approximately 60 and it is hoped that this will increase with out-of-state membership.

Meetings are held every fourth Saturday of each month at 7:30 p.m. in the Clarion Ledger Focus Building, 2915 Terry Road, Jackson, MS. A bi-monthly newsletter is distributed to all members. Various activities such as field trips and holiday festivities are an added bonus to those living within driving distance.

All persons, amateur or professional, sharing an interest in the field of herpetology are invited to visit or join. State membership dues are $10.00 individual and $15.00 family. Out-of-state membership is $7.00. Institutional membership is $20.00.

For more information, contact:

Mississippi Herpetological Society
Post Office Box 8087
Jackson, Mississippi 39204
(609) 373-3135 ●

AMPHIBIAN ECOLOGY GROUP IN BRITAIN

The Amphibian Ecology Group consists of representatives from all the centres in Britain where active research into amphibian ecology is taking place. The group first came together at Leicester in January 1982, and the second meeting took place at the University of Wales Institute of Science and Technology Field Centre, Newbridge-on-Wye in October 1982. The aim of the meetings is to provide a forum for the exchange of ideas on amphibian ecology, in order to define more clearly research objectives and to standardise methods and procedures. It is hoped that meetings will take place in the autumn each year, when accounts of the preceding summer's field work will be presented. The next meeting will be held at Monks Wood Experimental Station, Abbots Ripton, Huntingdonshire, England, in the autumn of 1983. Anybody wishing further details of the group or a report of the October 1982 Amphibian Ecology Seminar should contact Dr. S.P. Gittins, Department of Applied Biology, UWIST, King Edward VII Avenue, Cardiff CF1 3NU, Wales, or through the British Herpetological Society, c/o Zoological Society of London, Regent's Park, London NW1 4RY, England. ●

A DICEPHALIC KING SNAKE *(Lampropeltis getulus yumensis)* FROM ARIZONA

In the autumn of 1977, a dicephalic male kingsnake *(Lampropeltis getulus yumensis)* was collected at South Mountain, Maricopa County, Arizona. The hatchling was later loaned to the Animal Resource Center where one of us (L.N.) has cared for the snake. It is presently on display in the Life Science Center at Arizona State University.

The specimen is referred to Cunningham's (1937) "anterior dichotomy" class due to extent of duplication and separation of the vertebral columns (Fig. 1).

The total length of the snake is 56 cm, the tail length is 10.6 cm, with neck lengths of 8 cm and 9 cm. There are 8 (right head) and 11 (left head) separate ventrals on each neck. These scales appear creased and deformed. Loose folds of skin are present posterior to the hump which represents the vertebral junction (Fig. 2). Also, the ventrals located between the external junction and 3 cm posterior to the vertebral junction are distinctly narrower than mid-body scutes (1.5 vs. 4.0 mm). The two vertebral columns are parallel, with the right one being slightly elevated above the left just before turning left and down to the junction. This results in the humpback appearance (Fig. 2). Cunningham (1937) presents 2 photos (Plate X L, figures 116 and 117) showing a similar hump in *Opheodrys aestivus*.

Shaw and Campbell (1974) described head dominance in both feeding and movement among four dicephalic kingsnakes at the San Diego Zoo. In this specimen, both heads have complete and separate control over movement, and no definite dominance has been demonstrated by either head. This is apparent when one head is eating and the other attempts to move after another food item. When the two heads attempt to go in opposite directions, the neck muscles just quiver as if strained and the back arches. While one head is feeding, the other will try to take the food away which has resulted in numerous scars on both heads. For this reason, both heads are fed simultaneously. To prevent the mice from clogging the alimentary junction, one mouse is presented head first, the other laterally. The snake is fed four mice (5-8 g) every 10 days. Mice are killed just prior to feeding, which discourages constriction.

Figure 1. A two-headed *Lampropeltis getulus* showing vertebral junction.

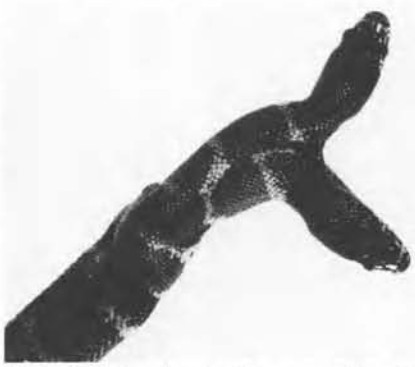

Figure 2. A two-headed *Lampropeltis getulus* from Maricopa Co., Arizona.

Although Shaw and Campbell (1974) reported a *Lampropeltis getulus* that survived for 6 years in captivity, most reported dicephalic snakes die as hatchlings (Lasher 1980, Klauber 1956, Branch 1979). As of July 1981, this snake has survived for at least 3 years and 8 months.

ACKNOWLEDGMENTS

This snake was collected by and generously loaned to Arizona State University by Ann Bassett. The photograph and radiograph were taken and developed by Roy A. Barnes, Anthropology Department, Arizona State University.

SSAR SILVER ANNIVERSARY COMMEMORATIVE PRINT

As part of the 25th Anniversary Celebration the Society has issued a beautiful *full-color* print of a Gila monster, taken from a watercolor drawing by the noted wildlife artist David M. Dennis. The print measures 11½ by 15¼ inches (29 by 38.5 cm) and is printed on a very heavy acid-free paper stock so that it can be framed or used as a poster.

The edition is strictly limited to 1000 copies, most of which were distributed at the Annual Meeting in Raleigh in August, but some copies remain for sale on a first-come, first-served basis. Prices are $10 each postpaid, or $8 each in quantities of 10 or more. Send orders to Dr. Douglas H. Taylor, SSAR Publications Secretary, Department of Zoology, Miami University, Oxford, Ohio 45056, U.S.A. Checks should be made payable to "SSAR"; payment in U.S. funds, please. ●

LAMPREYS IN THE DIET OF HELLBENDER *Cryptobranchus alleganiensis* (DAUDIN), AND THE NEUSE RIVER WATERDOG *Necturus lewisi* (BRIMLEY)

In 1972 William E. Brode (pers. comm.) stated that lampreys occur in the diet of Tennessee River *Cryptobranchus*, but there is nothing in the literature concerning this phenomenon. Crayfish are the major dietary item of hellbenders throughout their geographic range (Nickerson & Mays, 1973). However, some specimens in Missouri populations of *C. alleganiensis* have contained large numbers of lampreys. One series that contained lampreys was collected in early April 1974 from the Niangua River, Dallas County (Osage River drainage) by James Caliando (Robert Wilkinson, pers. comm.). Nickerson collected another series on 21 April 1977 in the Big Piney River, Texas County (Gasconade River drainage) from which was preserved a sample of regurgitated lamprey.

The Texas County sites are within the range of three lamprey species, but only the Northern brook lamprey, *Ichthyomyzon fossor*, is recorded from either river (Pflieger, 1971). Although the Big Piney River lampreys were partially digested, William L. Pflieger (pers. comm.) identified one as an adult *I. fossor*. April is the breeding season for *I. fossor* at this latitude (Pflieger, 1975), and presumably *Cryptobranchus* are harvesting the lampreys in their breeding pits.

No food studies have been published on the Neuse River waterdog, *Necturus lewisi*, but studies now being made of this species at the North Carolina State Museum of Natural History show that small aquatic invertebrates, some terrestrial invertebrates, and some fish and salamanders are included in the diet. Unlike *N. maculosus*, *N. lewisi* only occasionally feeds on crayfish.

Predatory behavior of the waterdog on fish and other vertebrates in the laboratory is also being studied. Specimens of the Least Brook Lamprey, *Lampetra aepyptera*, were collected in shallow breeding waters of a small tributary of the Neuse River in April 1979 by David S. Lee and David Carroll. Three adults of this small species were introduced into a 165 gallon aquarium containing three adult *N. lewisi* (two females and a male). The lampreys took refuge beneath large pebbles and rocks, and on the same evening they were observed depositing eggs. One of the *N. lewisi* converged on the area. Upon approach of the apparently foraging waterdog the lampreys withdrew under the stones, but the waterdog wedged its head under the stones and sucked a lamprey into its mouth. The *Necturus* then forcefully pulled the lamprey from the stones and consumed it from the head end, swallowing it alive and whole. No lampreys could be located in the tank twenty-four hours after their introduction.

A MELANISTIC *Elaphe vulpina* FROM OHIO

Certain taxa of snakes, such as *Elaphe o. obsoleta* and *Coluber c. constrictor*, are known to normally undergo a post-embryonic ontogenetic increase in melanism. Other species such as *Sistrurus c. catenatus* and *Crotalus horridus* (Klauber, 1972) have local populations which do the same. Yet other species, such as *Thamnophis sirtalis*, have populations with a high proportion of individuals which have melanism present from birth (Blanchard and Blanchard, 1941). However, for most aberrantly melanistic snakes mentioned to date (for example: *Storeria d. dekayi*, Heckman, 1960; *Nerodia f. fasciata* and *Lampropeltis c. calligaster*, Mount, 1975; *Agkistrodon c. contortrix*, Fitch, 1959; *Crotalus v. viridis* and *C. v. oreganus*, Klauber, 1972; *C. intermedius omiltemanus*, Armstrong and Murphy, 1979; *Micrurus fulvius tenere*, Gloyd, 1938) it has not been determined whether the abnormal amounts of black pigment are present at birth or are post-embryonically ontogenetically acquired. Catling and Freedman (1977) report, however, that aberrant melanism in *Thamnophis butleri* is present from birth. In this paper we report an ontogenetic increase in black pigmentation for an aberrantly melanistic *Elaphe vulpina gloydi*.

On 26 May 1977, the senior author collected a female *E. v. gloydi* at a locality within the Toledo City Limits, Lucas Co., Ohio. Upon its capture the specimen was observed to possess several unusual characteristics. These were the presence of a nodular spinal deformity *ca.* one-third of the way down the dorsum, the unusual shape and appearance of the head, and the uncharacteristically dark coloration of the skin. The specimen at this time was *ca.* 35 cm long (total) and the dorsal coloration was a dusky chestnut, slightly lighter than the rows of dark brown dorsal blotches. This is in contrast to the normal color pattern at this size of dark brown blotches on a straw-colored ground. After examination, the specimen was released where captured.

On 4 June 1978, the specimen was recaptured at the same site. The presence of the same combination of aforementioned aberrant characters in this specimen precluded the possibility of two snakes being involved. It was now *ca.* 80 cm long (total) and was nearly uniformly flat dark brown along the dorsum; the blotches were most evident anteriorly. The ventral pattern consisted of a yellow ground and a concentration of dark brown squares along the sides of the ventrum. This pattern of ventral blotch distribution is also uncharacteristic of the species. The amount of melanin in this specimen was evidently increased between the two capture dates. The scale and blotch counts of the specimen are normal for the subspecies.

A shed epidermis from this snake was saved and shows the same preponderance of dark coloration as does the specimen itself. The presence of the abnormal amount of melanin in the epidermal cells is expected for such cases of morphological melanism as reported herein (Bagnara and Hadley, 1973, p. 31).

This specimen was found in a heavily disturbed industrial area where *E. vulpina* is fairly common. The amount of chemical contamination of the environment probably is moderate to heavy. In this locality other oddly colored *gloydi* have been found which have had unusually pinkish or orange ground colors, though these are not so striking as the melanistic specimen. Also, *Thamnophis butleri* from this locality sometimes exhibit unusually reddish lateral coloration. It should be noted that the authors have never seen unusually colored *E. v. gloydi* or *T. butleri* from any of numerous other localities within northwestern Ohio. It is possible that these color aberrations are due to chemical contamination of the environment, although it remains unproven.

Besides indicating that melanin content in aberrantly melanistic snakes may be post-embryonically ontogenetically increased, this specimen also appears to represent the first reported aberrantly melanistic specimen of the genus *Elaphe*.

We wish to thank H.B. Bechtel for reviewing the manuscript, and M. Nasatir and the Department of Biology, University of Toledo, for the use of their photographic facilities.

AQUATIC BEHAVIOR OF COLLARED LIZARDS, *Crotaphytus c. collaris*, FROM ARKANSAS

Burt and Hoyle (1934) provided a detailed account of aquatic behavior by a collared lizard which dove into the water, remained submerged and retreated under a rock. In addition, Werth (1973) reported aquatic behavior by a collared lizard from Kansas and suggested that this phenomenon (aquatic utilization) might be a common occurrence in lizards. Ventures into water by lizards of xeric habitats apparently are uncommon; however, Dillon and Baldauf (1945) and Stille (1947) reported this unusual behavior in *Cnemidophorus sexlineatus*. Here, I report on aquatic behavior by collared lizards from Arkansas and suggest possible explanations for this unusual event.

The study site was an abandoned rock quarry located in northcentral Arkansas (Izard County), 0.8 km east of Myron (T18N, R7W, Sec. 26). The area was characterized by outcroppings of cherty limestone upon which collared lizards bask. The center of the site was a rock quarry pit containing a moderately-deep pool of water (mean depth ($\bar{D}$) = 1.8 m). Surrounding the perimeter of the pond were escarpments situated directly above open water.

As anticipated, while attempting to capture lizards to obtain cloacal temperatures, individuals escaped by retreating under rocks or habitually running to a nearby suitable outcropping. Escaping lizards seldom ran over three meters. Alternately, some individuals remained atop large rocks and seemed to "ignore" the presence of intrusion. On six occasions (4, 11, 31 July; 6, 12, 22 August 1979) between 1300 and 1430 hrs, adult male collared lizards ran to the periphery of the quarry pond, hesitated briefly, and jumped into the water. These lizards had adequate room to run elsewhere but instead took refuge in the pond. Upon entering the water, lizards either: (1) briefly remained motionless while filling their lungs with air and then slowly floated back to shore or (2) quickly returned to shore by actively swimming without pausing to allow for lung expansion. It took approximately one to two minutes for lizards to reach the shoreline and, at times, their heads were briefly submerged.

It is difficult to determine whether the lizards "chose" to escape in the quarry pond rather than in their terrestrial surroundings. This type of concealment would lower their body temperature, may have caused a temporary thermal shock, and in turn, restricted mobility. Recorded body temperatures of 138 active *C. c. collaris* ranged from 30.5 to 41.5° C, $\bar{x}$= 37.4 ± 2.6° C (McAllister, 1980). Body temperatures obtained from six lizards which quickly swam back to shore ranged from 21.5° to 24.0° C, $\bar{x}$= 22.7 ± 0.8° C. During these observations, water temperatures at a depth of 10 cm ranged from 20.0° to 23.5° C in this portion of the quarry pond.

Interestingly, during the study recapture data for 43 marked lizards indicated a loss of 48.8% (9 males, 12 females) of the animals before they entered winter dormancy (McAllister, 1980). An occasional loss may have resulted from lizards which entered the quarry pool and may have simply drowned or were eaten by the resident predacious fish population of largemouth bass *(Micropterus salmoides)*. Although no actual predation was observed, adult *M. salmoides* will occasionally consume frogs, mice, and other small animals that swim or fall into the water (Pflieger, 1975).

ACKNOWLEDGMENTS

This information is based on a portion of a thesis prepared in partial fulfillment of the requirements for a Master's degree in biology at Arkansas State University. I thank my major advisor, Dr. V.R. McDaniel, and other members of my thesis committee for encouragement, suggestions, and assistance in field work. I also thank Drs. T.L. Beitinger and E.G.Zimmerman, North Texas State University, for helpful comments on the manuscript. I further wish to acknowledge that this study was supported in part by a grant from the Arkansas Herpetological Society.

THE REPRODUCTIVE BIOLOGY OF THE INDIAN SKIPPER FROG *Rana cyanophlyctis*

Frogs and toads have been important resources for developmental and other studies for a number of years all over the world. However, the study of Indian amphibians has not equalled the progress made in recent years in other vertebrate groups (Daniel, 1963). This is especially true in the area of developmental biology due to the lack of standardized methods for maintenance and reproduction of the amphibians of India. For the first time, we have been able to successfully domesticate the Indian skipper frog *Rana cyanophlyctis*.

The skipper frog is common in India and is mainly aquatic. Ramaswami and Lakshman (1954) had indicated the suitability of this frog for embryological studies in India and had successfully induced ovulation. In our laboratory, we have been able to standardise the methods for maintenance, husbandry and multiple ovulations of this species.

Sexually mature frogs are collected during the breeding season. They are numbered, toe clipped and ovulated by induced ovulation. The animals are maintained under conditions standardised by Mohanty-Hejmadi (1977a and b). Up to 15 specimens can be kept in an aquarium (about 45 cm by 25 cm and 25 cm deep) containing conditioned tap water. Rocks are placed at one end providing a dry surface. The water is changed daily. The frogs are force-fed with goat liver. They are kept under two food regimes: one group is fed daily and the other group is fed on alternate days.

Starting one month after collection, the frogs are given half of a female (or one male) heteroplastic *Rana tigerina* pituitary or one female (or two male) homoplastic pituitary to induce ovulation. The unmacerated pituitaries are injected into the peritoneal cavity by a #18 gauge needle. Onset of egg release varies, beginning as soon as six and as late as 16 hr after injection depending on the temperature. On rare occasions, the eggs are released after a second pituitary injection, 24 hr after the first injection. In these frogs, eggs are released 30 hr after the first injection.

Table 1. Ovulation and survival record of laboratory conditioned *Rana cyanophlyctis*.

Food	N	Ovulation Frequency[1] (%)						No. of eggs[2]		Survival
		1	2	3	4	5	6	Control	Expt.	%
Alt. days	15	0	45.5	54.5	0	0	75.0	296	274.5	87
Daily	15	17.0	14.0	20.0	26.6	33.0	75.0	296	438.0	60

[1]Percent frogs ovulating in each of 6 attempts.
[2]Average per ovulation.

The frogs which are fed daily can be ovulated at 30 day intervals (Table 1). However, the percent of death is high. Frogs fed on alternate days ovulate less frequently, however, the survival is better. Fecundity is directly controlled by nutrition; the frogs fed daily yield more eggs in comparison to the controls (eggs ovulated just after collections).

The animal is hardy and easy to take care of. Eggs can be obtained throughout the year. An average female (snout-vent length 6.0 cm) can produce 150-500 eggs at each laying. The eggs are 1.0 mm in diameter and are suitable for experimental manipulations. The methods for rearing and life cycle have been reported (Mohanty-Hejmadi and Dutta, 1980). The larvae grow to 52 mm in total length and weight is approximately 1100 mg. The average snout-vent length at metamorphosis is 17 mm and weight is 750 mg.

We have successfully domesticated the Indian skipper frog for the first time in India. We recommend daily feeding for short term study and alternate day feeding for long term. The procedures developed by us can provide encouragement for workers to use amphibians for teaching and research in India.

ACKNOWLEDGMENT

This work has been supported by CSIR, India. The authors would like to thank Dr. B. K. Behura, the Head of the Department of Zoology for his encouragement throughout this study.

MORPHOLOGIC EVIDENCE OF TOXIC SALIVA IN COLUBRID SNAKES: A CHECKLIST OF WORLD GENERA

Reports of toxic colubrid snakebites involving humans and prey animals have appeared sporadically during the past one hundred years. Recent interest in colubrid toxinology is reflected by several reviews (Gans, 1978; Kochva, 1978; McKinstry, 1978; Mebs, 1977; Mebs, 1978; Minton, 1976; Minton, 1978; Minton and Mebs, 1978). This interest parallels recent reports, some widely distributed, of mild to severe or even fatal envenomations in man (Anonymous, 1975a, 1975b; Grogan, 1974; Mamonov, 1976; Mebs *et al.*, 1978; Mittleman and Goris, 1978).

The primary morphologic indicator of toxicity in colubrids is thought to be the presence of Duvernoy's gland. This branched tubular salivary gland is "located in the postocular region, reaching the angle of the mouth posteriorly and the level of the eye dorsally" and drains to the posterior maxillary teeth. Serous cells, rich in protein, are the main secretory cells of Duvernoy's gland; however, mucous cells, rich in carbohydrates, may also occur, particularly in the duct system (Kochva, 1978). Aaron Taub (1967), in his definitive monograph on the occurrence and comparative morphology of Duvernoy's gland, lists this gland in 100 of 112 colubrid genera examined. While the actions of Duvernoy's gland secretions are very incompletely studied, the above reviews indicate that mild reactions in humans usually involve inflammation while the most severe reactions involve serious impairment of the hemostatic mechanisms leading to hemorrhage. Reactions in prey animals involve a variety of findings.

The secondary morphologic indicator of toxicity in colubrids is the presence of enlarged rear maxillary teeth, either grooved (opisthoglyphous, commonly termed rear fangs) or solid (aglyphous). These dentition types may vary within a given genus, *e.g.*, *Rhabdophis* and *Erythrolamprus* (Malnate, 1960; Peters and Orejas-Miranda, 1970).

While Duvernoy's gland is present in many colubrids, regardless of tooth form, it is absent in some which lack enlarged rear maxillary teeth.

This checklist of colubrid generic names, based on the above morphologic indicators, is divided into five tables. Dentition, being more completely documented than the presence of Duvernoy's gland, forms the basis for Tables 1-4 as follows: Tables 1 and 2, opisthoglyphous genera, New and Old World; Tables 3 and 4, aglyphous genera showing marked enlargement of the rear maxillary teeth, New and Old World. References for accepted generic names and dentition as well as notations of Duvernoy's gland presence and geographic distribution are included. Table 5 lists the aglyphous genera of the world, with unmodified rear maxillary teeth, examined by Taub (1967) for Duvernoy's and supralabial glands. References for dentition and geographic distribution are included. Listing of a given genus indicates that one or more species of the genus has the characteristic in question. Dual listing indicates that the dentition type varies among the species of the genus or that authorities differ as to their description of the dentition type. In some cases a generic name was traced from an earlier synonym.

Two African genera of venomous snakes, the elapid genus *Elaps* and the viperid genus *Atractaspis* (FitzSimons, 1974), will probably be accepted as colubrids. Two recent reports (Branch, 1981; Harding and Welch, 1980) group *Atractaspis* with the colubrids. Since this matter seems unsettled, (Bourgeois, 1968; Kochva *et al.*, 1967; Kochva and Wollberg, 1970; McDowell, 1968), I have not included them in the checklist but do mention the likelihood of future inclusion.

This checklist is provided as an aid to those conducting literature and laboratory investigations in colubrid toxinology and to those collecting and keeping colubrid snakes for a variety of purposes. The importance of awareness as to the toxic nature of certain colubrid snakes is illustrated by the recent sale of dangerously toxic *Rhabdophis* specimens, as harmless snakes, in England (Mather *et al.*, 1978).

Given the fluid nature of colubrid taxonomy and nomenclature, the data in this checklist are subject to change. Thus this checklist should be periodically revised. Any suggestions for a future revision will be gratefully received.

Geographic distribution abbreviations from Bellairs (1970) are as follows: Af., Africa south of the Sahara; As., Asia; Aus., Australia; E.As., East Asia, mainly China; E.I., East Indies including southern Malaya, Borneo and Indonesia; Eu., Europe; Mad., Madagascar; N.Af., Africa north of and including the Sahara; N.Am., North America including Mexico; Phil., Philippines; S.Am., southern America including Central America (south of Mexico); S.As., southern Asia including India and Ceylon, Burma, the Indo-Chinese region and in some cases, southern China; W.As., western Asia including Arabia, Persia, West Pakistan, *etc.*; W.I., West Indies. For some genera, sources other than Bellairs were used to provide geographic distribution data. Abbreviations for these data conform to those of Bellairs.

Other abbreviations used in the tables are: S, D-S, serous Duvernoy's gland; SM, D-SM, serous-mucous Duvernoy's gland; S-M, supralabial gland, mucous; S-MS, supralabial gland, mucous-serous; ND, no data (in reference to Taub, 1967); NP, not present.

Reference notations (numbers not in parentheses) in the tables correspond to the numbered reference citations.

ACKNOWLEDGMENTS

This study was supported by a Behrend College Research and Scholarly Activities Fund grant. The author wishes to thank the following investigators for their generous support in reviewing portions of the manuscript: Donald G. Broadley, Simon Campden-Main, Ronald I. Crombie, Frances I. Irish, Alan E. Leviton, Sherman A. Minton, Jr., Findlay E. Russell, Alan H. Savitzky, Hobart M. Smith, and Paulo E. Vanzolini. These acknowledgments are given with the understanding that the accuracy of this paper is solely the responsibility of the author.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

HATCHING IN CAPTIVITY OF A CLUTCH OF *SCELOPORUS UNDULATUS HYACINTHINUS* EGGS

This paper reports the hatching of a clutch of eggs laid by a captive female *Sceloporus undulatus hyacinthinus*. The female was captured by noosing in rural Cape Girardeau County, Missouri, on 7 May 1979. At the time of capture, the specimen weighed 17.1 g and had a snout-vent length of 73 mm. She was placed in a plywood box 3' x 4' x 1' which contained rocks, sand and constantly dripping water, was heated by two 250-watt infrared lamps (12:12 L:D) and was illuminated by a 20-watt growlight (14:10 L:D). This enclosure provided a range in surface temperature between 20 and 46° C and contained eleven conspecifics of varying sizes and both sexes. All lizards were fed crickets dusted with calcium-phosphorus powder 4-5 times a week.

On 21 May 1979, this female made a number of trial excavations in warm, dry sand before laying her clutch of 17 eggs in the damp sand beneath the rock upon which the water was dripping. The temperature of the sand was 26.5° C. The excavation process involved an initial burrowing with the nose, with forelimbs folded back along the sides of the body. The propulsive force of this "bulldozing" was hindlimb movement and sinusoidal undulations of the trunk. This was followed by active digging, in which the female would use her forelimbs to dig out the sand, pushing it back to the hindlimbs, which would then kick it further back out of the way. The female would periodically interrupt these activities, turn

around and back into the burrow, with her head and forelimbs sticking out, remain a few seconds in that nearly horizontal position, then reposition herself for more digging. Eventually this head-out position was assumed during ovipositing. The eggs were deposited approximately 4 cm beneath the surface of the sand, resting on the wooden floor of the enclosure. It is not known if this is the normal depth of oviposition for this species, but it is unlikely that deeper oviposition would occur in the wild, since the animal's size and position during egg-laying would preclude achieving much greater depth. Also, Crenshaw (1955) reports that eggs of *S. u. undulatus* laid in artificial nests containing 3 inches of wet sand were found at depths of from 1-1½ inches. It should be noted that the clutch site contained the only damp sand in the enclosure; presumably it was chosen for its dampness rather than its temperature, although a systematic series of choices was not made available to the lizard.

After the eggs were exposed *in situ* by gently scraping away the sand, they were lightly marked on their uppermost surfaces with a soft lead pencil to insure that their subsequent placement would be in the same gravitational orientation. The oval eggs were a creamy white color. Only five of the 17 eggs were weighed and measured, to minimize dessication. Table I summarizes those measurements.

Table I. Dimensions of five *Sceloporus undulatus hyacinthinus* eggs measured from a clutch of seventeen.

	Mean (± 2 s.e.)	Range
Length (mm)	11.6 (± 0.48)	11-12
Diameter (mm)	7.4 (± 0.48)	7-8
Mass (g)	0.34 (± 0.02)	0.32-0.35

A round, thin-walled plastic container (such as a commercial cottage cheese container) was used as an incubation chamber. It was prepared by cutting three equidistant holes in its bottom edge and filling it with wet Vermiculite® as an incubation medium. (I have since become aware of Tryon's (1975) formulation of water and Vermiculite®, which is more precise.) After draining the excess water via the holes, the eggs were buried in the moist Vermiculite® and the container was placed in a large glass jar covered with a watchglass and incubated at 33-34° C under a 12:12 L:D regimen. These conditions were maintained for 20 days until a move to a different facility necessitated the eggs being kept in an environment where temperature varied from 20-29° C with a 14:10 L:D cycle.

On 5 July 1979, 45 days after being laid, 16 of the 17 eggs hatched. Emergence of each hatchling followed the same general sequence: the head emerged through a slit in one end; the animal then lay motionless for 15-45 minutes, after which considerable struggling liberated the anterior half of the body from the shell. This was followed by another rest period of about 30 minutes (although one individual remained motionless for four hours). A final period of activity resulted in the animal becoming entirely free of the shell, after which it lay motionless for 5-10 minutes. The transition from this quiescence to the first running activity was often so rapid that it was impossible to predict and difficult to observe. After each hatchling emerged and dried, it was weighed and measured, the results of which are summarized in Table II.

Table II. Dimensions of hatchlings of *Sceloporus undulatus hyacinthinus*. (n = 16)

	Mean (± 2 s.e.)	Range
Snout-vent Length (mm)	23.38 (± 0.44)	22-25
Tail length (mm)	25.00 (± 0.70)	22-27
Mass (g)	0.48 (± 0.01)	0.45-0.55

Following the measuring, each hatchling was toe-clipped for identification and placed in a wooden box with a heat source (heating pad under one end and 150-watt flood light over the same end), sand, and water dripping on a rock. The latter item is quite important, since these lizards rarely drink from a dish. The hatchlings were fed a variety of insects (2-5 mm long) taken from net sweepings. The yolk sacs began to dry and atrophy within one hour of placement in the box.

One hatchling was placed in the adult enclosure and was promptly attacked by an adult and partially swallowed. Had it not been rescued, the hatchling would have been eaten. It is thus necessary to house the captive hatchlings separate from the adults to avoid such cannibalism.

The increase in mass from freshly-laid egg to hatchling (compare Tables I and II) is undoubtedly due to the uptake of water by the eggs, which is quite common in reptiles (Bustard, 1965; Cunningham and Huene, 1938; Gordon, 1960; Shaw, 1952. Also, Marion, *et al.* (1979) present a brief but clear discussion of previous research done on water absorption by reptile eggs.) Under the incubation conditions described herein, the eggs apparently took up water. Fear of disturbing the embryos precluded measuring the eggs after the initial observations, but periodic visual examination showed an apparent increase in diameter and length consistent with Shaw's (1952) reported increases in egg dimensions of many lizard species, including *Sceloporus undulatus elongatus*.

ACKNOWLEDGMENTS

The author wishes to express his thanks to Dr. Fred Janzow for assistance in collecting and enthusiastic support and to Daniel Green and Todd Robitsch for helpful discussions on problems of incubation and general care. Special thanks go to Mr. Tom R. Johnson of the Missouri Department of Conservation, for invaluable suggestions on lizard husbandry, to Dr. James Edward Heath, Department of Physiology and Biophysics, University of Illinois, Champaign-Urbana, Illinois, for critical reading of the original manuscript, and to Dr. Norman Braasch, Department of Biology, Southeast Missouri State University, for helpful suggestions during manuscript revision. Observations reported herein were made at facilities provided by the Department of Biology, Southeast Missouri State University, Cape Girardeau, Missouri, and the Department of Physiology and Biophysics, University of Illinois, Champaign-Urbana, Illinois.

CAPTIVE REPRODUCTION IN AN AUSTRALIAN ELAPID SNAKE *Pseudechis colletti*

Collett's snake *(Pseudechis colletti)* is a large (up to 2.5 m) elapid snake of central Queensland. The restricted distribution and rarity of this species have resulted in a dearth of scientific information; the only data on reproduction are reports of viviparity by Worrell (1963) and Gow (1976). Our observations on three pairs of captive specimens indicate that *P. colletti* is oviparous.

Data are most extensive for one female and two male *P. colletti* collected from blacksoil plains near Nonda, Queensland, in June 1980. The snakes were maintained in separate cages at normal temperatures and photoperiods. Immediately after she had sloughed on 30 September 1981, the female (total length 137 cm) was introduced to the cage of a male (190 cm). Copulation commenced immediately (1700 hrs) and continued until at least 2400 hrs when observations terminated. The snakes had separated when next observed (0800 hrs). The same two snakes were placed together on 9 October 1981, and copulation lasting more than two hours was observed.

The female was placed with the second male (160 cm) on 30 October 1981, and again copulated. Bleeding from the female's vent was noticed during the first two matings.

Seven elongate eggs (total mass 250 gm) were laid on 28 December 1981. The female weighed 400 gm after oviposition, indicating a Relative Clutch Mass of 0.63. The eggs were incubated in damp Vermiculite® (50% water by weight) at 27 to 30° C, and hatching commenced after 67 days. Three eggs were slit on 7 March, one on 8 March, and one on 9 March. Dissection of the two remaining eggs on 10 March revealed dead full-term embryos, both of them males. The live young comprised three females and two males. These snakes did not fully emerge from the eggs for 12 to 15 hours after initial slitting of the shells. The neonates averaged 28.3 cm SVL (range 28.0 to 30.0 cm) and 24.0 gm (range 19 to 29 gm). Their first sloughs occurred on 22 to 24 March, approximately 15 days after hatching.

The second breeding pair of *P. colletti* were collected near Nonda in October 1978. The female (137 cm total length) and male (213 cm) were placed together for the first time on 9 August 1979, and were found *in copulo* 90 minutes later. Mating continued for five hours. After the snakes separated, slight bleeding from the female's cloaca was observed. The female continued to feed while gravid (food offered and accepted on 21 July, 2 August, 19 August, 13 October). The female sloughed on 17 August and 26 October; the posterior part of her body was noticeably swollen for about nine days prior to egg-laying. Oviposition of 14 eggs occurred between 0100 and 0600 hrs on 10 October. One egg spoiled and was discarded, and the other eggs incubated on moist Vermiculite® at approximately 31° C (range 29.5-32.0° C). The eggs were large with a mean length of 5.5 cm (S.E. = 0.1), and width of 3.2 cm (S.E. = 0.04). Three eggs hatched on 5 December, six on 6 December, and four on 7 December. Hence, incubation comprised 56 to 58 days. After slitting the eggs, most neonates remained inside their shells (with heads protruding) for approximately 45 minutes before emerging completely. Neonates showed coloration similar to, but more vivid than, their parents. The hatchlings averaged 37 cm in total length, and 25 g in weight. Two hatchlings and two eggshells were placed in the Queensland Museum (registration numbers J 37327-37330).

A third pair of snakes (the female from 10 km WSW of Aramac, Qld.) bred successfully on five occasions. Mating was observed in August (1977) and September (1976, 1978). Oviposition occurred on 30 December 1973, 8 December 1976, 30 November 1977, December 1978 (exact date unknown), and 26 November 1979. Hatching was recorded on 5-9 March 1974 (incubation 66-70 days) and 11 February 1977 (65 days). Clutch sizes of 12 eggs (one year) and 13 eggs (three years) were recorded.

These data from the three breeding pairs of *P. colletti* are consistent with respect to oviparity, seasonal timing of mating and oviposition, clutch sizes and incubation periods. Until recently, authorities have considered all *Pseudechis* species to be viviparous (McPhee 1959, Worrell 1963, but see Gow 1976). Ovipar-

CLEAR PLASTIC HIDING BOXES AS A HUSBANDRY DEVICE FOR NERVOUS SNAKES

Many elapids and other active snakes emit defensive and/or escape-searching behaviors so frequently in captivity that good husbandry dictates the use of dark hiding boxes in order to maintain the animals in top condition (Kauffeld, 1969). Recently we had a similar experience with our colony of *Naja mossambica pallida*. The snakes were too nervous and active to keep without hiding boxes, and providing these boxes meant that the animals could not be seen. Temporary removal of the hiding boxes during experimental sessions resulted in extreme defensiveness, spitting at the observer, and inattentiveness to experimental manipulations (*e.g.*, introduction of prey items). Experience with these and other snakes suggested to the authors that two sensory components might influence the snakes' selection of a hiding place, one being visual (seeking darkness) and the other being thigmotaxic (seeking an enclosed space where the walls contact the snake).

Accordingly, we constructed small hiding boxes made of clear plastic, and a small area in one corner was taped to provide slight shading without making observation impossible (see Fig. 1). These boxes were immediately utilized when they were introduced to snake cages. Defensiveness and escape-searching disappeared completely. The benefits have been even greater than we expected: Snakes are visible at all times, and their presence, health, and behavior can readily be observed. Experimentation no longer requires the disturbing removal of the hide box, and the snakes seem to be habituating to human observers (perhaps because the snakes frequently see humans through the clear plastic). Even though the snake can see and be seen through this box, the animal nonetheless uses the box just as it previously used dark boxes of the sort described by Kauffeld (1969). Removal of the clear box results in the same kind of defensive reactions as were seen upon removal of a dark box, indicating that the clear box has much the same "security value" to the snake.

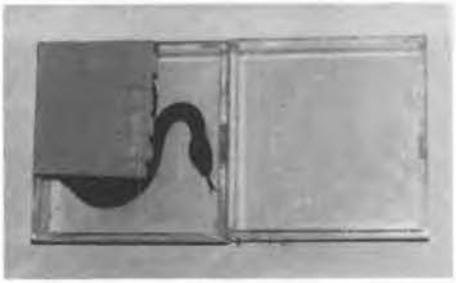

Fig. 1. A specimen of *N. m. pallida* in a resting coil inside of a clear Plexiglas box. Two boxes are present, one with the corner taped.

In addition to these husbandry advantages, the clear boxes facilitate research designed to separate the relative effects of darkness and thigmotaxis on the hole-seeking behavior of cobras (see Fig. 2). Experiments are currently in progress to determine snake preference when offered both dark and clear boxes. As indicated by Figure 2 snakes do not automatically and exclusively prefer the dark box. Hence, it is possible that thigmotaxic cues are not entirely subordinate to scototaxic ones.

Fig. 2. The black box has been turned over to illustrate the entrance hole.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Houston Zoological Gardens, P.O. Box 1562, Houston, Texas 77001.

ANURA

RANA PIPIENS (Leopard Frog). **PREDATION.** During a recent study of the trophic ecology of largemouth bass, *Micropterus salmoides*, in Lake Rebecca, Hennepin County, Minnesota (Cochran and Adelman, Env. Biol. Fishes, in press), evidence for a seasonal pulse of predation upon leopard frogs was obtained. Young-of-the-year frogs were first observed along the shoreline of the lake on 20 July 1978. Since reproductive activity was not noted during the spring, and no tadpoles were ever collected during seining, electrofishing, or fish stomach sampling, it is likely that these frogs had dispersed from a reproductive site elsewhere, probably from marshland to the southwest. This would be consistent with Merrell's (1977, Occas. Pap., Bell Mus. Nat. Hist., No. 15) generalization that young frogs disperse to the shores of large

permanent water bodies from breeding sites in temporary ponds without fish.

Although they were observed in the immediate vicinity of the shoreline for the rest of the season, frogs were found in only 2 of 404 bass sampled on 8 dates from 17 May-29 August 1978. On 21 September, however, frogs were found in 4 of 84 stomachs, while on 5 October, 11 frogs were found in 10 of 52 stomachs. Predation on leopard frogs by bass in early autumn was probably enhanced by increased availability due to two factors: (1) a die-off of aquatic macrophytes around the edge of the lake, noted in progress as early as 21 September, may have in effect removed a "buffer strip" which served to minimize contact between bass and frogs earlier in the season (fragments of reeds or other vegetation were found in five stomachs which contained frogs), and (2) the frogs appeared to spend more time in the water with the onset of cooler weather, as also noted by Merrell *(ibid.)*. A sample of frogs collected on 5 October from 1200-1230 were all captured in approximately 15 cm of water with air and water temperatures at 12° C and 14° C respectively. That frogs overwintered in the lake was indicated by the finding of large numbers of dead individuals on the bottom in shallow water after a severe winterkill in March 1979.

Twelve frogs collected on 5 October had a mean snout-vent length of 46 mm (range: 40-56 mm), while 6 relatively intact frogs found in stomachs had a mean snout-vent length of 60 mm (range: 48-73 mm). The range in total length of bass which contained frogs was 206-473 mm. One bass which contained a frog on 21 September contained 2 frogs when recaptured on 5 October.

SERPENTES

CHARINA BOTTAE BOTTAE (Pacific Rubber Boa). **FOOD.** On 11 June 1982 a *Charina bottae bottae* was collected under a piece of bark. The site was in a pine forest in Amador Co., CA (along West Panther Creek, 15.8 miles NE of Pioneer on Hwy 88 then 1.8 miles SE on a paved road, 1475 m). Within the next five hours the captive snake regurgitated an adult female *Ensatina eschscholtzi platensis* (Sierra Nevada Ensatina Salamander) along with a clutch of 12 eggs. The specimens are deposited in the MVZ collection at the University of California, Berkeley.

It appeared that the *Ensatina* had been swallowed head first, because there were signs of partial digestion of the head. There were no signs of digestion on the eggs, suggesting that they were eaten last. *Charina* had previously been reported to eat rodents and lizards (Stebbins, R.C. 1954. Amphibians and reptiles of western North America. 536 p.), but neither salamanders nor their eggs have been reported previously.

Like other plethodontid salamanders, female *Ensatina* brood their eggs, and egg brooding is presumed to increase survivorship of the egg clutch. At the same time there is a disadvantage in that female salamanders and their eggs are subject to predation. Shaffer (1978, Copeia, 1978:268-277), in a study of 10 species of neotropical plethodontid salamanders, found that in nine out of 10 cases the frequency of tail autotomy was greater in females than in males and he suggested that this was due to predatory attacks on brooding females. The above case of a *Charina* eating a female *Ensatina* and her clutch resulted in a loss of fitness for the individual.

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer). **COLORATION.** An amelanistic partial albino *C. c. flaviventris* was previously reported from Kansas (Capron, 1977, Newsletter Kansas Herp. Soc. 22:7) and a photograph of that specimen was published (Miller, 1978, Herp. Review 9(2):78). Recently, two amelanistic partial albino *C. c. flaviventris* were donated to the Fort Worth Zoological Gardens, Fort Worth, Texas. On 13 August 1977 a specimen was captured in SW Fort Worth, Tarrant Co., Texas. A second specimen (Figure 1) was captured on 22 August 1981, 5 km W Springtown, Parker Co., Texas. Both specimens were apparently born the summer of capture, based on the presence of prominent umbilical scars. The 1981 specimen was 24.7 cm total length at the time of capture.

Both specimens had a normal pattern for juveniles of this species. The ground color was a very pale yellow-orange and the normally brown body markings were orange.

The specimens have been deposited in the Vertebrate Collection, University of Texas at Arlington (UTACV 7197 and 10497).

Figure 1. Amelanistic partial albino *Coluber constrictor flaviventris*. Parker Co. Texas. UTACV 10497.

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer). **REPRODUCTION.** Incubation of eggs collected from wild and captive squamates outside a natural nest is common (Murphy and Collins, 1980. Reproductive Biology and Diseases of Captive Reptiles, SSAR Cont. Herpetol. #1). Most frequently, these eggs are obtained after natural oviposition. Thus, the egg shell and shell membranes are completely developed. Incubation to hatching of eggs obtained prematurely by either exogenous hormone (oxytocin or arginine vasotocin) administration or dissection from pregnant females is rarer (Bellairs, 1971. Developmental Processes in Higher Vertebrates. Univ. Miami Press, Coral Gables, Florida). We report here a case of successful incubation of eggs removed from a pregnant, road-killed *C. constrictor*.

An adult, female (71 cm total length) *C. constrictor* was found on 14 June 1982 approximately 19 km W of Newton, Harvey County, Kansas. The female was exhibiting spastic contractions when found and had the cardiac and upper oviductal region of the body crushed. Palpation of the abdominal cavity indicated that the female was gravid. Upon dissection, a clutch of 13 eggs was exposed, 11 of which were not damaged. The eggs appeared to be nearly complete as the egg case was opaque, chalky-white and flexible. Eggs were manually palped from the oviduct and collected in a clean plastic bag. Following transport to the laboratory, the eggs were buried in sterilized (by boiling) peat moss in a sterile 4 liter jar. The substrate was heated to 28-30° C using a 40 watt incandescent bulb suspended approximately 25 cm above the jar. Substrate was kept slightly moist to the touch.

Following an incubation period of approximately six weeks, one young *C. constrictor* hatched on 27 July 1982. One additional egg had a full-term embryo (stage 37: Zehr, 1962. Copeia 1962:322-329) which did not hatch and the remaining eggs exhibited little development (Zehr stages 15-20). Embryonic death of the remaining eggs may have been due to technical problems (burying of eggs/acidic environment due to use of peat moss) not related to the inherent viability of the eggs. These data suggest that some eggs may be saved from road-killed or dying pregnant specimens if (1) they are obtained soon after the mother's death and (2) the shell is fairly well developed. How early during the gestation period (shell development stage) eggs can be removed and still complete embryonic development is unknown. However, eggs in the final stages of shell development can be incubated with a fairly high likelihood of success. The neonatal specimen was deposited in the Museum of Natural History, University of Kansas (#192442).

Submitted by **LOUIS J. GUILLETTE, JR.** and **W. PETER SULLIVAN,** Department of Biological Sciences, Wichita State University, Wichita, Kansas 67208, U.S.A. ●

ELAPHE OBSOLETA LINDHEIMERI. (Texas Rat Snake). **SIZE.** The largest known specimen of *Elaphe obsoleta lindheimeri* was 84.75

in. (Conant, 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton-Mifflin). A specimen collected by Cory Fincher in Gretna, LA (a suburb of New Orleans) measured 86 in., thus being the largest known specimen by 1.25 in. The snake was measured live on a flat surface, photographed and released.

Submitted by **ROBERT A. THOMAS** and **VERNON FRILOUX,** Louisiana Nature Center, 11000 Lake Forest Blvd., New Orleans, Louisiana 70127. ●

LAMPROPELTIS GETULUS HOLBROOKI X SPLENDIDA (Speckled X Desert Kingsnake). **COLORATION.** An amelanistic partial albino specimen (75.2 cm total length) of *Lampropeltis getulus holbrooki* X *splendida* was reported by Carpenter (1957, Herpetologica 13:78). On 20 April 1972 an amelanistic partial albino female *L. g. holbrooki* X *splendida* was captured by Clarence R. Brown at the Dallas Naval Air Station, Dallas Co., Texas, and donated to the Fort Worth Zoological Park, Fort Worth, Texas. Based on photographic evidence, the specimen was *ca.* 60 cm total length when captured, and was probably entering at least its second year of life.

Figure 1. Amelanistic partial albino *Lampropeltis getulus holbrooki* X *splendida*. October 1981. 95.0 cm.

The specimen (Figure 1) is completely lacking in melanin and is white except for the retention of normal bright yellow spots and bars on the venter and dorsum and a yellow ring along the inner circumference of the iris. The eyes are otherwise pink. Additional albino specimens resulting from a breeding program are similar in appearance except a few individuals have pale yellow markings.

Upon death, the specimen will be deposited in the Vertebrate Collection, University of Texas at Arlington.

Submitted by **GARY CARL** and **RICHARD HUDSON,** Department of Herpetology, Fort Worth Zoological Park, Fort Worth, Texas 76110. ●

LAMPROPELTIS GETULUS HOLBROOKI (Speckled Kingsnake). **REPRODUCTION.** On 1 June 1982, a gravid *Lampropeltis getulus holbrooki* was collected off of Rt. 87, 2.7 miles east of the junction of Rt. 3 in McCurtain County, Oklahoma. The snake was found coiled inside a hollow log among tall grass on the road side. The snake measured 94 cm SVL (108cm TL).

The snake was housed in a 61 x 33 x 31 cm wooden cage with a glass front at the University of Oklahoma Biological Station, Kingston, Oklahoma. The bottom of the cage was covered with newspaper and a water dish was present in the cage. On 24 June 1982 the snake deposited 18 eggs on the newspaper. All but two of the eggs were adherent in a single mass. Egg length ranged from 27.8 to 32.0 cm ($\bar{x}$= 29.32 cm) and combined weight of the eggs was 127 g.

The eggs were numbered and placed in a one gallon glass jar which had a 4 cm base of Vermiculite®. Water (0.25 L) was added to the Vermiculite® for moisture. The jar was kept tightly closed and was opened intermittently for air circulation. Incubation temperature ranged from 28 to 33° C. On 13 August 1982, at the University of Oklahoma Animal Behavior Laboratory, the eggs were removed from the jar, reweighed (combined wt. of 144.1 g) and placed in an 18.9 L aquarium with a moist Vermiculite® base and glass top.

The young snakes began to hatch on 14 August 1982 after 51 days of incubation. Grimpe and Benefield (1982, Herp. Review 12(3):80) have reported an incubation period of 51 days for a clutch of 9 eggs. Carpenter (pers. comm.) has reported incubation periods of 49 and 54 days. All of the eggs except one had hatched by 17 August 1982. The unhatched egg started to discolor and was opened on 24 August 1982 to reveal a dead mature embryo. The SVL of the 17 live young (7 females, 10 males) ranged from 21.1 to 23.4 cm ($\bar{x}$= 22.42 cm). TL ranged from 24.6 to 27.5 cm ($\bar{x}$= 26.14 cm) and individual weights ranged from 4.6 to 6.5 cm ($\bar{x}$= 5.66 cm). Grimpe and Benefield *(ibid.)* reported for 9 young mean SVL, TL, and weight of 20.5 cm, 24.1 cm, and 6.3 g respectively. Carpenter (pers. comm.) had reported means for SVL, TL, and weight for newborn *L. g. holbrooki* of 23.62 cm, 27.30 cm, and 6.85 g respectively for a clutch of 11 young and 21.54 cm, 24.74 cm, and 5.09 g respectively for a clutch of 8 young.

This is the highest number of eggs reported for a single clutch of this subspecies of *Lampropeltis getulus*. Wright and Wright (1957, Handbook of Snakes of the U.S. and Canada) list a range of clutch size for *L. g. holbrooki* of 6 to 14 eggs. Anderson (1965, The Reptiles of Missouri) also notes 14 eggs as the maximum clutch size for this snake. Carpenter (1958, Herpetologica 14(2):113-115) has reported a female *L. g. holbrooki* (SVL= 98.1 cm; TL= 105.3 cm) laying 16 eggs.

I wish to thank Dr. Charles C. Carpenter for use of his data and James J. Krupa for discovering the gravid snake.

OPHEODRYS VERNALIS (Smooth Green Snake). **REPRODUCTION.** On 16 August 1982 I found a clutch of 23 snake eggs underneath a weathered black plastic "garbage" bag on Islesboro Island, Penobscot Bay, Waldo Co., Maine. The bag, which contained decomposed bovine manure, had been placed at the collection site the previous summer by the property owner. The eggs were loosely adherent to each other but many separated when they were picked up. One egg that appeared to have a thinner shell than the remainder was accidentally broken at the time of collection; it contained an almost fully developed but apparently non-viable *Opheodrys vernalis* embryo. This embryo and the shell were discarded. The remaining eggs were placed in damp sphagnum moss in a glass jar. Slits first appeared in some of the eggs on 19 August and by the next day 15 had hatched. The six ♂♂ ranged in total length from 134 to 154 mm (mean 146.8), the nine ♀♀ from 133 to 154 mm (mean 147.6). I opened one of the remaining seven eggs on 24 August; it contained a fully developed ♂ embryo. Another five eggs hatched on 26 and 27 August. This second hatching consisted of three ♂♂ (total length 140 to 152 mm, mean 147.7) and two ♀♀ (148 and 151 mm). The one egg that failed to hatch was opened and found to contain an early embryo embedded in coagulated yolk. Beneath the same plastic bag was a juvenile *Opheodrys vernalis*, a juvenile *Thamnophis sirtalis*, and two gravid *Storeria occipitomaculata*, all common species on Islesboro.

Wright and Wright (1957. Handbook of Snakes. Vol. 1, p. 558) reported that clutch sizes for *Opheodrys vernalis* range from three to twelve with an average of 7.4 eggs. It would appear that the present instance is an example of communal egg laying in *Opheodrys vernalis* involving at least two, but more probably three or more females. Communal egg laying in this species has not previously been noted.

SONORA MICHOACANENSIS (Ground Snake). **COLORATION.** Color pattern variation in this little-known species has been described in detail by Echternacht (1973, Breviora, no. 410). Of the 31 specimens known at that time, a single specimen (FMNH 37141) is described and figured as being patternless except for a dark mask on the head and a dark nuchal band, characteristics that are relatively invariant in this species.

On 15 July 1981, the senior author and party collected a specimen of *S. michoacanensis* 12.9 km E Apatzingán, Michoacán, that closely matches the pattern described for FMNH 37141, which was also collected at or near Apatzingán. This specimen (LSUMZ 40701) is a female having a total length of 335 mm (285 mm SVL, 50 mm TL) and exhibiting the following scalation characters; 179 ventrals, 39 caudals, 7/7 supralabials, 8/8 infralabials, and a temporal formula of 1-2 on both sides. The color pattern consists of a black head cap covering most of the dorsal head scales, followed by a white collar confluent

WE ARE PLEASED TO ANNOUNCE the availability of an extraordinary series of wildlife prints by David M. Dennis. These meticulously painted portraits are full-color reproductions of the original watercolor drawings, each printed on a sturdy paper stock measuring 20 by 24 inches and suitable for framing. Prints are *strictly limited to an edition of 500 copies, personally signed and numbered by the artist.* Because of the relatively small size of the edition, these prints represent a collectible investment and a source of lasting enjoyment as well. They would also be ideal for gifts.

Mr. Dennis is widely known to the scientific community as an artist specializing in watercolors of lower vertebrates and insects. His self-taught artistry is complemented by his academic training in biology and his personal field experience with each of the animals he paints. Mr. Dennis earned his undergraduate degree in zoology from The Ohio State University in 1966 and since then has held a succession of positions as biological illustrator at the Columbus Zoological Gardens, the University of Kansas Museum of Natural History and now at Ohio State. He has illustrated many biology textbooks including one which he co-authored, but is perhaps best known to vertebrate biologists for the exquisite watercolors published in Duellman's *Hylid Frogs of Middle America* (University of Kansas Press, 1970) and in Smith and Brodie's *Field Identification Guide to the Reptiles of North America* (Golden Press, 1982). Originals of Mr. Dennis's watercolors have been exhibited in art galleries and museums throughout the United States and at scientific meetings. He has also won numerous awards for his artwork, most recently in an international competition at Cincinnati where he won the Josephine Rollman Award for "Best of Show".

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $29.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $53.95

36" Wide, 18" High, 19" Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

with the white supralabials, infralabials and throat. This collar is followed by a large black nuchal band (11-12 scales long dorsally), a small off-white band (2 scales long) and, finally, a small black band (2-3 scales long). All of the black bands are interrupted ventrally, being absent on the ventrals and first 3 dorsal scale rows. The rest of the body is unpatterned, and in life was a bright tomato red on the dorsum fading to a pinkish red on the venter and first 3 dorsal scale rows. The 9 anteriormost ventrals were white or pinkish continuous with the white on the throat. Most of the dorsal scales (except those on rows 1 and 2) have a black apical dot.

The specimen was collected in mid-afternoon on a hot, clear, sunny day preceded by heavy rain the previous evening. The snake was seen crawling among rocks a few yards from Mexican highway 120. Extensive rock turning had been carried out in the immediate vicinity about 15 minutes previously. This record is apparently only the second for the almost patternless morph of *S. michoacanensis*, and this report is the first to document its color description from life.

THAMNOPHIS ORDINOIDES (Northwestern Garter Snake). **BEHAVIOR.** *Thamnophis ordinoides* has been thought to be strictly terrestrial (Stewart, 1968, J. Herpetol. 2:71-86; Hebard, 1951, Herpetologica 7:61-62; Fitch, 1940, Univ. Calif. Publ. Zool. 44(1):1-50). Gayle Gillis and I have seen *T. ordinoides* swimming on two occasions, which indicates that *T. ordinoides* may not always be strictly terrestrial.

Late on a fall afternoon in 1980 we observed a *T. ordinoides* swimming in the Nestucca River at a point between Hebo and Woods, Tillamook County, Oregon. We came upon the swimming snake by canoe. Nothing was in sight that might have alarmed the snake into entering the water. It swam through moderate current to a small vegetated island composed of a partially submerged stump. The river is about 10 meters wide at that point.

Early on the afternoon of 11 July 1982, we saw a *T. ordinoides* near the middle of the Columbia Slough swimming toward the north bank midway between the Union Pacific and the Spokane Pacific and Seattle railroad bridges in the NE ¼ of the SW ¼ of section 5, T1N, R1E, W.M., Portland, Multnomah County, Oregon. We steered our skiff between the snake and the north bank. It dove about 5 meters from the skiff, surfaced a few seconds later on the opposite side of the skiff, and continued to the north bank. We followed it to the bank, where I captured it, verified its identity, and released it.

The Columbia Slough is about 110 meters wide at the site of our observation, and is deep enough for commercial tugs. Both north and south banks are very steep mud with overhanging blackberry canes. Emergent vegetation is absent. At the time of our observation the water was turbid and flowing very slowly upstream due to tidal influence. The wind was nearly calm and the water surface was glassy smooth. The sun was shining and the air temperature was between 27° and 30° C.

VIRGINIA V. VALERIAE (Eastern Smooth Earth Snake). **DEFENSE.** On 23 October 1982 on a woodland dirt road in Sinking Cove, Franklin County, Tennessee, my wife, Jean, and I found a 61 cm northern black racer, *Coluber constrictor*, attempting to swallow a 20 cm eastern smooth earth snake, *Virginia valeriae valeriae*. In the 5 minutes of my observation, the racer was having difficulty because its intended prey had formed a loop knot with its body. The racer was holding onto the oval knot, which was about 30 mm long and 12 mm wide, as measured with a field ruler. Both appeared sluggish although the weather was warm. When I touched the racer it released its intended prey and left the site. I placed the earth snake in a nearby sunny spot, where it released its knot and crawled under some dry oak leaves. Obviously this knot-formation, whether accidental or instinctive, had survival value for the earth snake. It is doubtful that the racer could have swallowed its captive in its knotted condition, but even a delay in the swallowing attempt enables more time for chance disturbances by other animals to cause the release of intended prey, as in this case. It is common knowledge that toads frequently will react to seizure by a snake by inflating their bodies. This action may not prevent their being swallowed, but the difficulty produced may allow time for life-saving disturbances. These observations are presented here because of their relevance to antipredator behavior and also in hopes that herpetologists, who have observed knot-forming in any species of snakes (including the earth snake) will communicate their observations.

TESTUDINES

PLATEMYS PLATYCEPHALA (Twistneck Turtle). **REPRODUCTION.** There is little published information on courtship and mating behavior in most South American chelid turtles. This paper describes such behavior in a captive pair of *Platemys platycephala*.

Origin of the specimens, obtained as adults, is unknown. Turtles were maintained in a 152 l tank, with a water depth of 13 cm and access to a lighted basking platform. Water was heated to 26° C, and incandescent lighting provided a 12 h light/dark cycle. Specimens were fed fish, earthworms, and chopped beefheart supplemented with vitamin powder (Theralin®, Lambert-Kay). The larger male (carapace length= 15.2 cm) was frequently separated from the female (CL= 13.4 cm) for several days; this seemed to stimulate courtship activity upon re-introduction.

On being placed in the tank, the male would pursue the female; the latter normally attempted to escape. He would immediately mount from behind and hook his hind claws under the edge of her carapace at the inguinal area. The front claws were employed to hold the anterior edge of her carapace. The front legs were also used to intermittently and alternately brush at the female's head in a rapid motion. This had the effect of forcibly keeping her head folded under her carapace.

The most active aspect of the courtship ritual involved the male extending his head downward and swinging it rapidly in a horizontal plane over the female's head, often with his chin barbels contacting the top of her head. The head-swinging sequence lasted from about 5 to 20 seconds, and often culminated with the male expelling streams of water at the female's head with pulsations of his throat (water movement confirmed by use of methylene blue dye). This head-swinging sequence is similar to that noted in courting *Pelomedusa subrufa* (Harding, J. 1981. Bull. Chicago Herpet. Soc., 16(4):86-94), but is much more rapid — almost spasmodic — in *Platemys*.

Rarely, the female would seem to cooperate with the male by extending her head upward against the male's chin barbels and following his head movements. More often, she would withdraw under her carapace, or try to escape. On a number of occasions, the female actually dragged the male out of the water by crawling up the basking ramp, effectively curtailing his efforts. The "leg swiping" and "head swinging" behavior by the male was noticeably increased in both frequency and intensity by any escape attempt of the female, and thus may at least partially be explained as ways to immobilize the female prior to copulation.

The male's long, almost prehensile, tail, and distally located anal opening certainly facilitates effecting cloacal contact and penile insertion. Actual copulation was not always obtained by the male *Platemys* during the observed courtship events, and seemed to require at least some acquiescence on the part of the female.

Submitted by **JAMES H. HARDING,** Cranbrook Institute of Science, Box 801, Bloomfield Hills, Michigan 48013 USA. ●

NEWSNOTES

CROCODILIAN PAPERS

The *Zimbabwe Science News* 16(9) September 1982 is an entire issue devoted to papers on crocodilians. This was in recognition of two major scientific gatherings held at Victoria, Zimbabwe this year dealing with crocodilians. ZSN is published by the Zimbabwe Scientific Association, P.O. Box 978, Harare, Zimbabwe. ●

SNAKE SEXUAL DIMORPHISM INFO SOUGHT

I am compiling information for a review of sexual dimorphism in snakes, with particular emphasis on differences between the sexes in body color, head shape and head size. Much information on this topic seems to be unpublished, although is common knowledge among reptile-keepers, or else is hidden in large taxonomic papers. I would be grateful for any information on the topic. Sources of information will be acknowledged.

COMPUTER REPORT AVAILABLE

The report of an NSF-sponsored committee on COMPUTER APPLICATIONS TO COLLECTION MANAGEMENT IN HERPETOLOGY AND ICHTHYOLOGY is available for distribution to interested parties. The report contains three main sections: (1) Issues involved in museum collection computerization projects, (2) Recommendations to the Biological Research Resources Program (NSF program sponsor of this work), and (3) Report of the site committee on a survey of collection computerization projects contemplated or underway including the results of a workshop convened at Washington, D.C. in March 1982. Individual copies of the report are available (*gratis*, but supplies are limited) from:

Dr. Robert H. Gibbs, Jr.
Division of Fishes
National Museum of Natural History
Washington, D.C. 20560 ●

AWARDS FOR STUDY AT ANSP

The Academy of Natural Sciences of Philadelphia, through its Jessup and McHenry funds, makes available each year a limited number of awards to support students pursuing natural history studies at the Academy. These awards are primarily intended to assist predoctoral and immediate postdoctoral students. Awards usually include a stipend to help defray living expenses, and support for travel to and from the Academy. Application deadlines are 1 April and 1 October each year. Further information may be obtained by writing to:

Chairman,
Jessup-McHenry Award Committee
Academy of Natural Sciences of Philadelphia
19th and the Parkway
Philadelphia, Pennsylvania 19103 ●

INCUBATOR DESIGNS

A project has been initiated by Marc Colen, a bio-medical engineer, herpetologist and member of SSAR to coordinate all interested parties in the design of an incubator for reptile eggs. The goal is to obtain design(s) that will incorporate all the features and capabilities deemed necessary while permitting low cost construction in a zoological park or laboratory workshop. There will be no cost to the participants. Resulting plans will be published or distributed gratis.

Please send a self-addressed stamped envelope to:

20137 Gilmore Street
Canoga Park, CA 91306 ●

VERMONT HERP INVENTORY

The Vermont office of The Nature Conservancy is conducting an exhaustive inventory of all herpetological collections, field notes, and albums which house Vermont records. We are interested in communicating with all individuals who might know:

a. The whereabouts of collections and notes of lesser known herpetologists or amateur collectors who collected in Vermont;

b. The names of herpetologists currently active as observers/collectors in the state of Vermont;

c. Individuals interested in reptiles and amphibians who frequent or live in Vermont and who might be willing to assist our ongoing search for selected species.

If you can be of assistance, please contact:

Marc R. DesMeules, Staff Biologist
The Nature Conservancy
7 Main Street
Montpelier, Vermont 05602

BOOK REVIEWS

Liste Der Rezenten Amphibien Und Reptilien. Testudines, Crocodylia, Rhynchocephalia by H. Wermuth and R. Mertens. 1977. Das Tierreich, W. De Gruyter, New York. xxvii + 174 pp. $105.00.

This paper-bound *das Tierreich* list is a revision of the comprehensive classification and synonym lists of the authors' (1961) earlier hardcovered book, which has been used widely as a reference for all turtles and crocodilians. That previous work was based upon a 1955 check list and urgently needed to be updated. It contains some crocodilian and chelonian surface anatomy, size information, identification keys, German common names, and drawings, all of which are absent from this present revision. However, to the new text the authors have added subfamilies and synonym lists of genera in addition to those for species. In essence the revision has been published primarily for specialized systematists. Final responsibility for this work is Wermuth's since the elder Mertens died 23 August 1975.

The current work opens with an extensive preface containing a discussion of revisions (and nonrevisions!), especially for turtles. No changes are given for the tuatara, and those several for crocodilians are based primarily on Fuchs' (1974) book which emphasizes lateral and ventral scales. There follows the systematic table of contents and systematic synonym lists with current geographical ranges of the species. Concluding the book is a twenty-two-page alphabetical index of scientific nomenclature.

Those hoping for a comprehensively revised taxonomy incorporating the latest published point of view or current usage may be disappointed because this work reflects the personal opinions of its compilers. It is clearly stated that their system of nomenclature and classification should have no official capacity. They say that their intention is to present the turtles as clearly as possible. They are not excited about reorganizing taxonomy on the basis of certain key characteristics (such as aural arterial canals, nasal anatomy or cervical vertebrae) but say they favor reliance upon a variety of characteristics including behavior and habitat. They are, we think, justifiably cautious about avoiding a system which will blow this way or that with every new wind, but we are concerned about some taxonomic selections made without adequate recognition of the conclusions from other international specialists. Although they indicate that any change in their framework must be justified objectively, we cannot help wondering just how much more evidence is needed to get the chelydrids, for instance, away from classification close to kinosternids, when biochemical, karyotypic and macroscopic anatomical data all indicate that they probably are not closely related.

Wermuth and Mertens accept McDowell's (1964) subfamilies Emydinae and Batagurinae but have not used them in a reclassification of genera within their Emydidae. We find

this regrettable and hope that whenever the next edition appears more flexibility will be demonstrated.

Although Wermuth and Mertens resist many changes that we feel are advisable, they do make others that are welcome: separation of *Pelusios subniger* and *P. castaneus;* inclusion of *Batrachemys* and *Mesoclemmys* with *Phrynops;* change of *Podocnemis cayennensis* to *P. erythrocephala.* In some cases they erect subgenera when others have suggested genus, for instance, *Geochelone* after Loveridge and Williams (1957) and *Rhinoclemmys* after McDowell (1964). Although we prefer the full status of these ranks, at least Wermuth and Mertens with their conservatism probably are moving in the right direction.

Currently it is popular to include the *Pseudemys* complex under *Chrysemys*, but, choosing to disagree with McDowell (1964) and Weaver and Rose (1967), the authors retain *Pseudemys* and also keep *Graptemys* separate from *Malaclemys.* Their conservatism here has proved wise based on recent evidence: Dobie (1981), Ernst and Ernst (1980), McKown (1972) and Vogt and McCoy (1980) support their reluctance to use these synonymies.

Regarding sea turtles, they have accepted the opinion of most specialists to accord specific rather than subspecific rank to *Lepidochelys kempi* and *L. olivacea.* Also the subspecies of *Caretta caretta* have been elevated to species.

Writings of those favoring resurrection of *Peltocephalus* for *Podocnemis dumeriliana (tracaxa)* and *Erymnochelys* for *Podocnemis madagascariensis* as well as some new descriptions [as Rhodin and Mittermeier's (1976) *Chelodina parkeri*] apparently are too recent to have been considered for inclusion in this book. Cunha's (1970) description of *Kinosternon scorpioides carajasensis* is not mentioned. Some other matters still requiring attention are to be found in Williams' (1962) review of the 1961 edition as well as in Iverson's (1979) critique of the current revision.

Since *das Tierreich* was published, the hardbacked *Encyclopedia of Turtles* (1979) by P.C.H. Pritchard has come out and this latter also contains a turtles-of-the-world check list. Pritchard has provided his justification for nomenclature used, and these names are more likely to be accepted by today's specialists, in particular turtle groups. Wermuth and Mertens' book is about one-fifth the size of the encyclopedia and more than double the price. For many engaged in turtle studies the Pritchard encyclopedia will suffice, but those involved in taxonomic work will find the Wermuth and Mertens' alphabetical index of scientific names and synonym lists of considerable value for turtles as well as for crocodilians.

Regarding crocodilians, the authors — to the chagrin of crocodilian specialists — have abandoned conservatism and embraced Fuchs' (1974) book, a publication of the reptile leather industry, as the authoritative source for most of their changes. Likewise the citation of "1975 *Alligata* Grawitz" as part of the *Alligator* synonomy is inappropriate. Grawitz's nonscientific article cannot be considered an authoritative treatise bearing on the taxonomy of the genus or species. Citing this sort of nonscientific publication is only a short step from citing newspaper articles as taxonomically important. At the same time, it is puzzling why Oliver's (1958) successful petition to the International Commission on Zoological Nomenclature to have the spelling of *Alligator mississipiensis* emended to *A. mississippiensis* is ignored, inasmuch as the single "p" repeatedly is being rediscovered by present day researchers.

The use of commercial crocodile skins in place of the usual holotypic specimens for the taxa *Caiman crocodilus matogrossiensis, C. c. paraguayensis, Crocodylus cataphractus congicus, C. niloticus africanus, C. n. chamses, C. n. cowiei, C. n. madagascariensis, C. n. pauciscutatus,* and *C. n. suchus* is without precedence. Despite the fact that Fuchs has a great deal of experience in identifying hides, it is highly unlikely that he can pull hides out of commercial lots and unfailingly assign them to the correct country of origin, much less particular drainage systems and lakes (F.W. King and P. Brazaitis, personal communication). How can a fully tanned, dyed, and finished hide taken from a commercial inventory, be used as a holotype? The exact locality of collection is not known. The collector is unknown. The date of collection is not known, and there are no skulls or dorsal scutellation available. Yet this is exactly what happened when these taxa were described by Fuchs (1974) and Fuchs, Mertens and Wermuth (1974). Additionally, voucher specimens of some of the new taxa were not available for deposition in a museum collection when the commercial hides were described and *nomen nudums* were created since no holotypes could be designated (see *Caiman crocodilus matogrossiensis* and *C. c. paraguayensis*).

Although most specialists regard *Crocodylus niloticus* as monotypic (Brazaitis, 1973; Neill, 1971), seven subspecies are presented here. Old names for these new descriptions are resurrected by the authors. While holotypes exist for these old taxa, they very well may not represent the same topotypic populations, demes, or morphotypes as the commercial hides used by Fuchs. In light of the concluding remarks by Fuchs, Mertens and Wermuth (1974) which suggest that much field work remains to be done before there is a final solution for *C. niloticus*, it is disturbing that Wermuth and Mertens simply accept Fuchs' stated characters for the subspecies he says he can recognize among the hides.

Also it is not clear why the authors separate *C. mindorensis* and *C. novaeguineae.* They were regarded as subspecies in their 1961 treatise. Again, without explanation, they accept Fuchs. The use of *C. p. porosus* and *C. p. biporcatus* is another head-scratcher which needs to be addressed properly.

The text fortunately appears relatively free of proofreading errors. On p. xv, line 18, there is accidental substitution of *Podocnemis unifilis* for *Podocnemis erythrocephala;* on p. xxii there is a "v" instead of "y" in *Cuora yunnanensis;* and on p. xxiii the "h" is omitted from *H. t. thurjii.* The alphabetic order for *Malaclemys terrapin tequesta* and *M. t. rhizophorarum* is reversed on p. xxiii and p. 46. The second "e" is missing from *Geoemyda (leytensis)* on p. 30. Under *Pseudemys ornata yaquia* (Legler and Webb's *P. scripta yaquia*), p. 57, the location was reported as "Conicarit", not "Conicarist".

In the forward, twenty-one papers or books are referred to using author(s) and years, but no group of complete references is listed. References are, however, given for three of these papers which include authors Wermuth and Mertens. It is true that most of the quoted works generally will be known by the specialists, and some references can be extracted from the synonym lists. However, we still feel that use of the publication would be facilitated by inclusion of a complete list of literature cited.

It could be argued that *das Tierreich*, which is just a world check list, should not be required to give reasoning behind all taxonomic decisions, but unless the explanations have been given elsewhere it would be appropriate for the authors to provide reasonable justifications for their taxonomy to a greater extent than they have done in this current revision.

An Annotated Bibliography of the Desert Tortoise, *Gopherus agassizi*, compiled by Judy P. Hohman, Robert D. Ohmart, and James Schwartzmann. 1980. Softbound. Desert Tortoise Council Special Publication No. 1. 121 pp. Available from: Desert Tortoise Council, 5319 Cerritos Drive, Long Beach, California 90805. $8.00 in US. Foreign orders add $1.00 for surface mail and $3.00 for air mail.

The desert tortoise is an increasingly uncommon element of the fauna of the Sonoran and Mojave Deserts. Its populations have been threatened by human interference for centuries and have been severely reduced or exterminated in many parts of its range due to the accelerating pace of agricultural and suburban development of these arid lands.

This publication is designed to provide a readily accessible source of information regarding the current level of knowledge on this species. This it does well, gleaning from wide-ranging sources spanning 100 years and organizing into 22 headings, information on taxonomic relationships, morphology, physiology, geographical distribution, natural history, ecology, conservation, and husbandry. The compilers have demonstrated their ability to summarize previous research in an outline form and telegraphic style without loss of content. This work appears at a time of intense efforts by the Bureau of Land Management and state conservation agencies in California, Arizona, Utah, and Nevada to ascertain the status of natural populations, restock former parts of their range with transplants, and establish preserves for *G. agassizi*. Much of this work has been published in state and federal publications that are not always easily obtainable. I found the summarization of these data particularly enlightening.

Although the compilers do not claim to present an exhaustive survey of the available literature on this species, they have managed to gather 212 articles including four overview papers or other bibliographies. In my opinion the literature-cited section is quite comprehensive and up-to-date. There are two points for criticism though. I found four papers listed in the text that are not found in the literature-cited section. Conversely I found seven articles in the literature-cited section not referenced in the text. Secondly while the function of an annotated bibliography may be to indiscriminately present a brief summation of the conclusions of previous workers, I found two instances where selective screening based on current information would have added to the quality evidenced elsewhere in the manuscript. These are: p. 10, "6. An additional species from Alamos, Sonora, Mexico, may be described in the future (Brame and Peerson, 1969)", and p. 29, "4. Based on genetic content tortoises may have a closer phylogenetic relationship to mammals than to birds." There is a fine distinction between condensation for maximum efficiency in conveying information and the loss of the contextual framework in which that information was originally imbedded. These are two examples where deletion of the conclusions would have been preferable to presenting possibly misleading information. The text is practically free from typographical errors (I found only two minor misspellings). In comparison to book prices in general these days, the price of $8.00 is not unreasonable.

Overall this work serves its intended purpose and will stand as a model for future efforts of this nature. I would like to see a similar treatment of the remaining three species of this genus.

Turtles in Kansas, by Janalee P. Caldwell and Joseph T. Collins, 1981. AMS Publishing Co., RR 6, Box 1, Lawrence, KS 66044. x + 67 pp. $5.25 postpaid.

The authors of **Turtles in Kansas** skillfully steer a course between a technical monograph and a popular handbook, and should reach a wide audience. At first glance it would seem that limiting the scope of the book to a small group of organisms (14 species) and a single state might be a mistake. But perhaps I underestimate the number of "turtle freaks" in Kansas, and the intensity of their interest. Moreover, this book will be of interest to turtle fanciers in the states surrounding Kansas that share much the same turtle fauna.

The authors provide a detailed species account for each of the fourteen species, and a spot distribution map. The accounts are divided into major topics such as description, habitat, reproduction, food habits, predators, distribution, similar species, and how to observe. These sections appear to have been compiled from the literature, with few original observations.

Each species is illustrated with at least one color photograph, and several with two. The photographs, by Joseph T. Collins, are mostly superb, although two of them (*Kinosternon flavescens*, p. 15; *Chrysemys picta*, p. 43) fail to show the diagnostic characters of these species. The color renditions are variable, but considering the cost of high-quality color printing these plates certainly are an adequate compromise.

There is a technical key to Kansas turtles, well-illustrated with line drawings, and a nontechnical key that the hobbyist can use to identify a living turtle in hand. A brief bibliography (15 titles) provides an introduction to both scientific and popular literature on Kansas turtles. A valuable addition would have been a brief review of techniques for the care of captive turtles.

It is difficult to criticize such a straightforward and potentially useful contribution, but there are two points that should be considered for future editions. First, the long-term value of the booklet could have been enhanced by anticipating taxonomic revisions in press or preparation as the manuscript was being written. Among these are the return to separate generic status for the sliders and painted turtle, *Pseudemys* and *Chrysemys*, and changes in the taxonomy of the false map turtles, *Graptemys pseudogeographica* and *G. ouachitensis*. The second point involves the lack of precision in the information contained in the species accounts. I was surprised to read, for example, that the map turtle is found in a "small area of the northeastern United States" (it ranges from the St. Lawrence River to Oklahoma, and from Alabama to Minnesota), that the Missouri cooter ranges from Virginia to Florida (it is not found east of Alabama), that *Graptemys pseudogeographica ouachitensis* "is found throughout the Sabine River system" (a drainage occupied by the subspecies *sabinensis*), and that the plastron of the western painted turtle has a bright red blotch (it is red with a black blotch). The species accounts contain far too many of these minor errors and inconsistencies, which could easily have been eliminated by having the manuscript reviewed by someone familiar with turtles and turtle biology.

The preparation of readable, authoritative interpretations of scientific knowledge is a responsibility too often avoided by professional biologists. Also, it is usually a profes-

sionally thankless task. I commend the authors of **Turtles in Kansas** for their effort, and I am certain that the turtle-lovers of Kansas will add their thanks for this worthwhile contribution.

Handbook of Reptiles and Amphibians of Florida. Part I — The Snakes, by Ray E. Ashton, Jr. and Patricia Sawyer Ashton. 1981. 176 pp. completely illustrated with color photographs. Windward Publishing, Inc., Miami, Florida. ISBN 0-89317-033-X. $9.95.

It is perhaps most appropriate that the authors of this well-organized book have selected snakes for the initial volume of their ambitious series, for snakes are, of all groups to be included in the series, the most fascinating to people. The Ashtons have done a remarkable job in organizing and presenting a wealth of information in concise, but highly readable accounts, which give the current scientific and standard common name, and contain sections on descriptions (both adults and juveniles), similar species, natural history and range. An account contains a map of Florida, with a dot in each county in which a given species is known to occur. In addition, one or more excellent color photographs (drawn from many sources) accompany each account, and the whole of them contained in the book are a beautiful display of the serpentine fauna of Florida. The texts and photographs are complemented by well-executed and useful drawings (by Renaldo Kuhler), and the bibliography is divided into four logical sections to allow easy access to pertinent literature. In summation, this book on Florida snakes is an excellent field guide, long awaited by herpetologists and naturalists, both in and out of Florida. I eagerly await the production of the companion volumes.

JOSEPH T. COLLINS

Lawrence, Kansas 66045

Complete guide to snakes of Florida, by William E. Haast and Robert Anderson. Phoenix Publishing Co., Inc., Miami, Florida. 139 pp. LC 81-80463.

Haast and Anderson have attempted to present the snakes of Florida in an effort "to assist the interested reader as well as the young student of Herpetology (the study of reptiles) with a general survey of the important points of identification and facts of habits and habitats relating to generalities of Florida's poisonous and nonpoisonous snakes." Casual perusal of the preceding quote should make the adult reader aware that any young student obtaining this book may learn an entirely new approach to writing English.

This book should never have been published. On its 139 pages, with a casual reading, I noted 18 misspelled scientific names (some with more than one variation), some new scientific name combinations *(i.e., Nerodia rigida, Nerodia septemvittata),* the erroneous inclusion of the "blue racer," *Coluber constrictor foxi,* as a member of the Florida herpetofauna, a mis-labelled "pink rat snake" photograph (page 57), and color photographs in the book of an overall poor quality throughout (except some of those provided by individuals other than the authors). The grammar throughout the book is atrocious, the organization of species accounts is simplistic, and the glossary contains terms that do not need definition (*i.e.,* abandon, description, egg, habit, lake, lung, muscle, pond, puncture, swamp, swelling, vomit, *etc.*) to anyone capable of reading.

The price was not given for this book (and I do not know it), but for herpetologists wishing to obtain information on Florida snakes, no price is needed.

Horned Lizards. Unique Reptiles of Western North America, by Wade C. Sherbrooke. 48 pp. Southwest Parks and Monuments Association, Box 1562, Globe, AZ 85501. $8.95 + $1.50 postage and handling.

This is a popularly written account of the identification, geographic ranges, habitats, and habits of the seven species of *Phrynosoma* in the USA. The text is a well-written and thoroughly researched account of horned lizard biology, including facts from even the latest studies. Numerous color photographs (88 according to the publisher) nicely supplement the text. Species are keyed to the photographs using head silhouettes unique to each. Sherbrooke also includes sections on the role of horned lizards in mythology and pottery of southwestern Indians, and on the current and future status of horned lizard populations, especially in the National Parks and Monuments.

This is a particularly well-conceived and executed view of horned lizards. The photographs are mostly excellent and the text has good organization and clarity, with a minimum of obvious errors. I noticed only one typographical error (p. 38). The price is a bit high, as with most other things these days, but even so this booklet would make an excellent gift for a budding herpetologist or for anyone interested in lizards.

A Report on the University of London Union Natural History Society Expedition to Greece 1980, by D. Stubbs, A. Hailey, W. Tyler and E. Pulford. 1981. Price $9.00 surface or $15.00 airmail from University of London Natural History Society, UL Union, Malet Street, W.C.1, London, England.

A well produced, comprehensive report has been prepared on the results of the University of London Union Natural History Society expedition to N.E. Greece in 1980, which describes an investigation on a dense population of *Testudo h. hermanni* near Thessaloniki. The various types of habitat in the site selected from a previous expedition in 1979 are described. A grid reference system was established for the quadrat sampling of tortoises. Size, weight and age are recorded for 791 animals and full mark-capture/recapture programmes initiated to determine the population size and density. Unfortunately, soon after the start of the study, local people rased the site to the ground by burning and rotivation in preparation for gaining planning permission for the building of holiday homes.

This is the first detailed study on any Mediterranean tortoise population. The effects of habitat destruction and fire on individual animals are also witnessed at first hand. The work highlights the problems concerning the conservation of tortoise species and their habitats and the impact of human pressure in the Mediterranean region for commercial purposes. The herpetofauna of the locality is also described and for selected sites in n.e. Greece generally. An annotated check list is given for the birds recorded during the investigation.

The report will be of interest and well worthwhile possessing for those involved with conservation work on reptiles, especially tortoises, and their habitats in southern Europe.

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific**

Names for North American Amphibians and Reptiles, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

CAUDATA

NECTURUS MACULOSUS (Mudpuppy). USA: MINNESOTA: Goodhue Co: collected in trash baskets at cooling water intake from Mississippi River to Northern States Power Company Prairie Island Generating Plant, approximately 6.4 km upstream from Red Wing (T 113N, R 15W, Sec. 4). 29 November 1982. K. N. Mueller. University of Wisconsin-Madison, Zoological Museum. One female (UWZH 22544), one male (UWZH 22545). The stomach of the female contained one *Hexagenia* mayfly naiad and the vertebral column of a small fish. First published record for Goodhue County (Breckenridge, 1944, Reptiles and Amphibians of Minnesota, Univ. Minnesota Press). Listed as hypothetical for southeast Minnesota by Minnesota Dept. of Natural Resources (1979, Guide to the Reptiles and Amphibians of Southeast Minnesota - Region 5). An average of 39 mudpuppies were collected annually from the trash baskets at the Prairie Island Plant from 1974 through 1980 (range: 8-116), primarily from mid-winter through early spring.

ANURA

RANA AURORA DRAYTONI (California Red-legged Frog). USA: CALIFORNIA: Santa Barbara Co: vicinity of Pelican Bay, Santa Cruz Island. 17 May 1919. Joseph R. Slevin. California Academy of Sciences (CAS 45230-32). First record for the Channel Islands. These specimens are entered in Slevin's field catalog in sequence with other amphibians and reptiles collected on Santa Cruz and Anacapa Islands on 16-17 May 1919, and were cataloged by Slevin at CAS. Inexplicably, Slevin omitted the locality from his review of western North American amphibians (1928. Occas. Papers Calif. Acad. Sci. 16:1-152), though there is no indication on existing records that the data were felt to be suspect. Slevin was noted for his careful work, and usually tagged and cataloged material daily while in the field, thus an error in locality seems unlikely. *Rana aurora* may be common yet pass undetected in small coastal drainages on the adjacent mainland, where it forages from concealment by night.

A substantial stream with permanent pools reaches the north coast of Santa Cruz Island just E of Pelican Bay; this is presumably Slevin's locality, and may still support a population of *R. aurora* in its rugged upper reaches. This record seems to have been overlooked previously through reliance on Slevin's (1928) listing being comprehensive for CAS holdings up to that time.

SAURIA

ALGYROIDES NIGROPUNCTATUS. GREECE: STEREA: Prefecture of Fokida: Province of Dorida: Tichio village, 27 km NE of Nafpaktos town. 14 May 1977. Collected by B. P. Chondropoulos and M. Doumas. Identified by B. P. Chondropoulos. Deposited in Zoological Museum of Patra University, Patra, Greece (Catalog number 3173). An adult male found basking on a vegetation-free accommodation roadside at 1130 hr. The present record extends the known species range at least 100 km eastwards (Ondrias, J. C., Liste des Amphibiens et des Reptiles de la Grèce, Biol. Gallo-Hellen., 1:111-135, 1968). First record for the Prefecture of Fokida.

Submitted by **B. P. CHONDROPOULOS,** Zoological Laboratory, Patra University, Patra, Greece. ●

GERRHONOTUS PAUCICARINATUS (San Lucan Alligator Lizard) MEXICO: BAJA CALIFORNIA DEL SUR: 1 km W San Ignacio. 18 September 1978. Collected by M. D. Mahlstedt from beneath fallen palm fronds at the edge of a stream bank. Identified by J. R. Ottley. Brigham Young University (BYU 34721). This specimen extends the range approximately 460 km northward from the La Paz area (Lais, 1976, *Gerrhonotus paucicarinatus*, Catalogue of American Amphibians and Reptiles, p. 188). Bostic (1971, Trans. San Diego Soc. Nat. Hist., 16:237-264) commented on specimens he designated *Gerrhonotus multicarinatus* ssp. from the Central Desert of Baja California del Norte and noted that those specimens manifest a number of meristic traits intermediate to *multicarinatus (G. m. webbi)* and *paucicarinatus*. The San Ignacio specimen was taken less than 150 km south of Bostic's (1971) record for *multicarinatus* at Miller's Landing (28° 28' N, 114° 05' W), and thus adds further weight to his suggestion of intergradation and possible conspecific relationship between the two species.

NERODIA SIPEDON SIPEDON (Northern Water Snake). USA: VIRGINIA: Pulaski Co: near confluence of Peak Creek and Claytor Lake. 7 September 1982. M. W. Klemens and P. R. Warny. Verified by R. G. Zweifel. American Museum of Natural History (AMNH 124932). First record for Pulaski County. (Linzey, D. W. and M. J. Clifford, 1981. Snakes of Virginia, Univ. Press of Virginia, Charlottesville, 159 pp.).

Submitted by **MICHAEL W. KLEMENS,** Department of Herpetology, American Museum of Natural History, New York, New York 10024. ●

NERODIA TAXISPILOTA (Brown Water Snake). USA: GEORGIA: Clarke Co: Sandy Creek near confluence with Oconee River, 0.8 km N Athens. 29 March 1982. C. D. Camp and M. C. Harrison. Verified by C. D. Camp. University of Georgia Museum of Natural History (UGMNH 17120). Specimen is an adult male. Immature specimen was collected and released by J. M. Howland 20 March 1982 at same locality. Represents range extension of two counties north of previous recorded localities.

Submitted by **CARLOS D. CAMP** and **JEFFREY M. HOWLAND,** Department of Zoology, University of Georgia, Athens, Georgia 30602. ●

RHINOCHEILUS LECONTEI LECONTEI (Western Long Nosed Snake). USA: ARIZONA: Coconino Co: 36° 58' N, 113° 19' W in Granite Park Canyon (east side of Colorado River). Elev. 442 m 27 April 1982. Not collected; see Figure 2. Individual was found in creosote/grassland habitat approximately 48 km downstream from the one other verified citing in Grand Canyon (Miller *et al.* 1982). Verified by O. Johnson, Northern Arizona University. (Miller, D. M., R. A. Young, T. W. Gatlin, and J. A. Richardson, 1982. Amphibians and reptiles of Grand Canyon. Grand Canyon Natural History Association, Monogr. No. 4).

Figure 2. Western Long Nosed Snake found at Granite Park Canyon, Arizona.

SISTRURUS CATENATUS (Massasauga). USA: TEXAS: Archer Co: 1.5 km S junction of FM 368 and FM 1954; 21 May 1982. Rocky Ward. Verified by E. G. Zimmerman. North Texas State University Herpetological Collection (NTSUHC no. R-682). This is the first record of this species in Archer County. *Sistrurus catenatus* has previously been recorded for all contiguous counties except Jack County (Raun and Gehlbach, 1972. Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2).

Submitted by **ROCKY WARD,** Department of Biological Sciences, North Texas State University, Denton, Texas 76203. ●

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). USA: VIRGINIA: Pulaski Co: 3.2 km SE Newbern, near Peak Creek. 5 September 1981. M. W. Klemens. Verified by R. G.

Zweifel. American Museum of Natural History (AMNH 123247). First record for Pulaski County. (Linzey, D. W. and M. J. Clifford, 1981. Snakes of Virginia, Univ. Press of Virginia, Charlottesville, 159 pp.).

Submitted by **MICHAEL W. KLEMENS,** Department of Herpetology, American Museum of Natural History, New York, New York 10024. ●

TROPIDOCLONION LINEATUM TEXANUM (Texas Lined Snake). USA: TEXAS: McMullen Co: 32.0 km SSW of Tilden on FM 624, 11.5 km west of intersection of Texas Rt. 16 and FM 624. Collected AOR after rain 21:30 hours, 14 September 1982. Paul S. Freed. Verified by Bern W. Tryon. Carnegie Museum of Natural History (CMFS 39871). This is the first record for this county and fills the gap between records from Bexar County (Raun and Gehlbach, 1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No.2) and Duval County (Benefield, G. E. 1979, Herp Review 10(3):103).

LIZARDS AND SNAKES FROM EASTERN LOWER EGYPT IN THE HEBREW UNIVERSITY OF JERUSALEM AND TEL AVIV UNIVERSITY, WITH RANGE EXTENSIONS [1]

The most thorough treatise of the reptiles of Egypt is Anderson's (1898), who details the morphology and localities of his specimens. Flower (1933) extends our knowledge of reptile distribution in Egypt, but often in general terms without precise localities. Some distributional data are incorporated in the ecological projects of Tortonese (1943-48, 1948), Khalil and Hussein (e.g. 1963), Hussein (e.g. 1964) and Hussein and Al-Badry (e.g. 1969). Localities are mapped by Marx (1968), but mainly from material obtained by the United States Naval Medical Research Unit No 3. In the Asian territory of Sinai, there was additional collecting in the Winter of 1956/57 (Werner, 1968), intensified during 1967-81 (Werner, 1973, 1980, in press; Zinner, 1974). Knowledge of reptile distribution in African Egypt has not progressed as rapidly. Hence, several records in the following listing of the lizards and snakes from Lower Egypt east of Nile in the Hebrew University of Jerusalem (HUJ), and Tel Aviv University (TAU), constitute significant range extensions. These are preceded by asterisks and their novelty is explained. Some of the specimens have been in the Hebrew University's Zoological Museum for some time; others were obtained through Israeli zoologists in Winter 1973/74. Spelling of locality names follows listings (or map) in "Egypt and the Gaza Strip, Official Standard Names Approved by the U.S. Board on Geographic Names" (Office of Geography, Dept. of the Interior, Washington, D.C., 1959).

**Stenodactylus sthenodactylus sthenodactylus* (Lichtenstein, 1823). HUJ-R 12779, SW (outskirts of) Ismailiyah [30°35'N 32°16'E], 22.XI.1973, don. E. Frankenberg; TAU-R 10472, Fa'id Airport, 4.XI.1973, don. A. Keller; TAU-R 10497 and 10498, 10 km W of Suez, 6.XII.1973, don. E. Shani. Anderson (1898) and Flower (1933) recorded this gekkonid only along the Nile Valley and west coast of the Red Sea and Gulf of Suez, where the northernmost specified locality is Ras Gharib (28°21'N); Marx (1968) has a specimen from Kutamiya (ca. 29°56'N, 31°49'E). The Ismailiyah specimen extends the recorded range by ca. 75 km E from the Nile Valley and 250 km N from Ras Gharib. The species is widespread in Sinai but has not been recorded within 50 km of Ismailiyah.

**Tropiocolotes nattereri* Steindachner, 1901. HUJ-R 12801, Jabal Ataqah [29°55'N, 32°20'E]: opposite of township of Ataqah [29°53'N, 32°28'E], 1.XXII.1973, don. A. Haim. Identified according to Leviton and Anderson (1972). Most authors (e.g. Guibé, 1966) do not distinguish between this and *T. steudneri* (Peters, 1869), but this possibly sibling species has been reported from the west and east sides of the Gulf of Aqaba (Flower, 1933), as well as Libya (16°00'E, 25°30'N - Schnurrenberger, 1962).

Agama pallida pallida Reuss, 1833 (about this terminology, see Werner, 1971). HUJ-R 1126, 5202 & 5203, Qassassin [30°49'N, 32°00'E], 10.IV.42, O. Theodor. This common agamid has since been reported from Qassassin and vicinity by Tortonese (1948).

Agama savignii Duméril & Bibron, 1837. HUJ-R 1144, Nafishah [5 km SW Ismailiyah], 20.IV.1942, O. Theodor. Anderson (1898) mentions 17 specimens from between Ismailiyah and Suez; Flower saw the species at Ismailiyah, and the nearest record of Marx (1968) lies ca. 85 km to the SSW of Nafishah.

Uromastyx aegyptius (Forskål, 1775). HUJ-R 1149, Cairo, July 1936, G. Witenberg. Known from the area.

Chalcides guentheri Boulenger, 1887. HUJ-R 1486, Cairo, July 1936, G. Witenberg. This skink is endemic to northern Israel and adjacent areas (mesic-Mediterranean), and our single record should be verified by another before acceptance.

Chalcides ocellatus ocellatus (Forskål, 1775). HUJ-R 1431, Ismailiyah, October 1942, O. Theodor; HUJ-R 12835, ca. 8 km S Ismailiyah (UTM 430377), 10.II.1974, don. E. Frankenberg; HUJ-R 13379, 13380 & 13381, Cheops pyramid, nr. Al Jizah, August 1976, R. Mathewson. Known from these areas.

Mabuya quinquetaeniata (Lichtenstein, 1823). HUJ-R 1429, Ismailiyah, October 1942, O. Theodor; HUJ-R 12736, 4 km SE Ismailiyah, 26.I.1974, don. U.N. Safriel; TAU-R 10487, Ismailiyah (fresh water lake), 12.XII.1973, don. R. Gainon. Specimen HUJ-R 12736 was more colourful than indicated by Anderson's (1898) fine plate 24 (Fig. 2). Anderson knows this skink only along the Nile; Flower (1933) adds that it appears to be extending its range along waterways; and Marx (1968) has a specimen from Abu Suwayr [ca. 15 km W of Ismailiyah]. This species is not known in Sinai.

**Mabuya vittata* (Olivier, 1804). HUJ-R 12834, ca. 8 km S Ismailiyah (UTM 430377), January 1974 (died 7.II.1974), don. E. Frankenberg. Anderson (1898), Flower (1933) and Marx (1968) record this skink from the Nile and Delta areas, but not from the Eastern Desert. It has not been found in Sinai.

Scincus scincus scincus (Linnaeus, 1758). HUJ-R 1359 & 5981-5985, Cairo, 1936, G. Witenberg; HUJ-R 13382, Cheops Pyramid near Al Jizah, August 1976, R. Mathewson. Known from the area.

Sphenops sepsoides (Audouin, 1827). HUJ-R 1478 & 5161-5164, Cairo, July 1936, G. Witenberg; HUJ-R 1480, Qassassin, June 1942, O. Theodor. Known from the general area; Marx's (1968) record nearest to Qassassin is from At-Tall al Kabir (15 km W of Qassassin) whence Tortonese (1948) also mentions it.

Acanthodactylus boskianus asper (Audouin, 1829). HUJ-R 1344, E of Cairo, July 1936, G. Witenberg; HUJ-R 1348 & 6151-6153, Cairo, July 1936, G. Witenberg. Known from the area.

Acanthodactylus scutellatus scutellatus (Andouin, 1829). HUJ-R 1318, nr Ismailiyah, 2.IV.1942, O. Theodor. According to Flower (1933), abundant about Ismailiyah, but Marx (1968) records no specimens between the Nile system and the Suez Canal. Found on the eastern shore of the Suez Canal (Werner, 1973).

**Eremias rubropunctata* (Lichtenstein, 1823). TAU-R 10533, W of Suez town, 16.XII.1973, don. E. Shani. The nearest earlier records are no. 3 tower on Cairo-Suez road (Flower, 1933) and Ain Sukhna [ca. 50 km SW Suez] (Marx, 1968). Known from NW Sinai.

**Eremias guttulata guttulata* (Lichtenstein, 1823). HUJ-R 12800, Jabal Ataquah [29°55'N, 32°20'E] (opp. Township of Ataqah [29°53'N, 32°28'E]), 1.XII.1973, don. A. Haim. Previous records are hard to evaluate because previous authors did not distinguish between this and *E. olivieri* (Haas, 1951).

Leptotyphlops cairi (Duméril & Bibron, 1844). HUJ-R 3031 & 3032, Cairo, December 1943 and 1944, H. Waly; HUJ-R 3710 & 3711, Abu Rawash (Al Jizah Prov.), 24.IX.1950, don. Chicago Natural History Museum. Known from both localities.

Coluber florulentus Geoffroy, 1827. HUJ-R 3309, Cairo, June 1936, G. Witenberg. Known from Cairo.

Coluber nummifer Reuss, 1834 (about this nomenclature see Werner and Avital, 1980). HUJ-R 3174, Cairo, August 1936, G. Witenberg. Anderson (1898) and Flower (1933) report this mesic-Mediterranean snake from the Cairo and Delta areas, but Marx (1968) records no specimens. Two are known from Wadi Feiran in Sinai (Barbour, 1914; Werner, 1973).

**Natrix tessellata tessellata* (Laurenti, 1768). HUJ-R 8580, freshwater canal ca. 8 km S Ismailiyah (UTM 430377), 9.I.1974, don. E.

(1) Dedicated to the memory of Professor Georg Haas, deceased 13.IX.1981, who broke the ground.

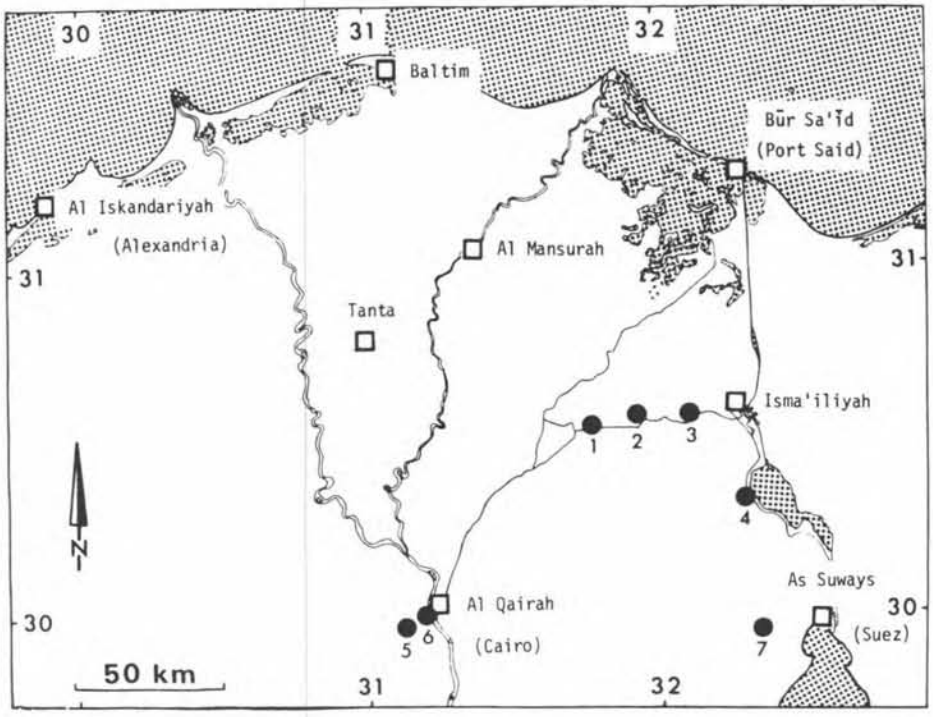

Figure 1. Sketch-map of eastern Lower Egypt with selected major components of the water system. Hollow squares indicate main localities for orientation. Solid circles indicate other localities of material: (1) At-Tall al Kabir, (2) Qassassin, (3) Abu Suwayr, (4) Fa'id, (5) Pyramids, (6) Al Jizah, (7) Jabal 'Ataqah.

Frankenberg; TAU-R 10470, Bitter Lake (W of Canal), 10.XI.1973, don. Y. Shoshani; TAU-R 10510, Ismailiyah, 30.XII.1973, don. M. Frianti; TAU-R 10526, Ismailiyah, 5.II.1974, don. Y. Shoshani. Anderson (1898), Flower (1933) and Marx (1968) know the diced water snake only from the Nile delta area; Tortonese (1948) only saw a specimen (not preserved) near Qassassin (halfway from the Delta area to Ismailiyah); there is no convincing record from Sinai (Hoofien, 1965; Werner, in press). Thus these specimens, presumably indicating a breeding population, constitute a range extension of ca. 105 km SE from the nearest record in the delta and ca. 230 km WSW from the nearest localities in Israel (Werner, unpublished).

Psammophis shokari (Forskål, 1775). HUJ-R 3227 & 3228, Cairo, July & August 1936, G. Witenberg; TAU-R 10455, Fa'id, 11.XI.1973, don. M. Cohen. Known from both areas. Because in Sinai *P. shokari* and *P. aegyptius* Marx, 1958, may be sympatric (Werner, 1973), most records antedating the description of the latter are useless. But Anderson (1898) lists scale counts by which the specimens from these areas are clearly assignable to *shokari*. Marx (1968), too, has material from near Cairo.

Psammophis sibilans sibilans (Linnaeus, 1758). HUJ-R 3240 (two specimens), Cairo, July 1936, G. Witenberg. Known from the area.

**Spalerosophis diadema cliffordi* (Schlegel, 1837). HUJ-R 8579, Fa'id, January 1974, don. E. Habibi; TAU-R 10475, Ismailiyah, 22. XI.1973, don. R. Gainon. According to Flower (1933) it is common along the Suez Canal; Tortonese (1943-48, 1948) observed the species at Tall al Kabir (45 km W Ismailiyah, 55 km NW Fa'id); Hussein (1964) obtained it ca. 75 km WSW of Fa'id; and Marx (1968) has specimens from ca. 30 km N and 50 km SW Fa'id. In Sinai known from 55 km SE Fa'id (Werner, 1973).

Telescopus dhara obtusus (Reuss, 1834). HUJ-R 3109, Cairo, 20.VIII.1930, O. Theodor. Known from the area.

Figure 2. *Mabuya quinquetaeniata*, HUJ-R 12736 (rostrum-anus, 87 mm; tail, 146 mm) from near Ismailiyah. Freshly dead, the coloration, in terms of Ostwald colors (Streller and Ostwald, 1939) was recorded as follows: Dorsum blackish brown, between 3pn and 4pl. Five lighter, light brown to beige longitudinal bands, between 2gc and 31e. Lemon yellow band covering supralabials (beginning gradually) and continuing through lower half of ear back to above axilla, about 2na. Sides of neck above this, dark black-brown, 6pn, speckled with light yellowish dots, 1ea. Gular area, and backwards to line between axillae, mottled blackish brown, 6pn, with yellowish, 1ea, and white spots. Belly very light grey, about d. (From a kodachrome diapositive.)

Cerastes cerastes (Linnaeus, 1758). TAU-R 3192, Cairo, Spring 1941, don. A. Shulov. ("at least three years old . . .died 5.I.1959" - from specimen label.) Known from the area.

In conclusion, of the 24 species included, the records of six constitute significant refinements of distribution maps or even range extensions. These, particularly the discovery near Ismailiyah of *Mabuya vittata* and *Natrix tessellata*, previously known only from the Nile and Delta, indicate the need for further herpetological field work in Egypt.

ACKNOWLEDGMENTS

I am deeply indebted to all persons who donated specimens to the Hebrew University and Tel Aviv University collections and to Prof. H. Mendelssohn for permitting my using the latter. For references to the literature (particularly the commonly overlooked papers by Tortonese) and other helpful comments on the manuscript I am much obliged to J.H. Hoofien, although I have not followed his advice concerning *Tropiocolotes*. I also thank E. Avital for curatorial help, A. Bouskila who helped me with the Italian literature, A.B. Niv for photographic assistance, P. Amitai who drew the map, and M. Rosenthal who coped with the typing.

BUFO HAEMATITICUS COPE: AN ADDITION TO THE ANURAN FAUNA OF HONDURAS

As part of a survey of the Río Platano area in eastern Honduras as a potential national park site, the senior author sampled the herpetofauna. In those collections are four specimens of the toad *Bufo haematiticus* Cope, 1862. These specimens represent a new record for this species in Honduras.

As indicated by Villa (1972), *B. haematiticus* is otherwise known to occur from Nicaragua to Colombia at low and moderate elevations. He also noted that in Nicaragua this toad occurs on the Caribbean versant in low, hot, and humid regions. The closest Nicaraguan record (Cerro Masique, Depto. Boaco) is approximately 315 to 340 kilometers SSE of the Honduran records (Jaime Villa, pers. comm.). In Costa Rica, Savage (1980) indicated the species occurs in the Caribbean and the southwestern Pacific lowlands and adjacent foothills. In Panamá, this toad apparently occurs on both versants (Breder, 1946; Taylor, 1952), as is also the case in Colombia (Cochran and Goin, 1970).

One specimen (UNAH 5446) was collected 14 May 1977 at Sin Sin Warra (15°40'N, 84°57'W) in the department of Gracias a Dios at an elevation of 70 meters. A second specimen (UNAH 5471) was found on 20 May 1977 at "Cañon del Chimelca" (15°36'N, 85°05'W) on the Río Chimelca near its confluence with the Río Platano in the department of Colón at an approximate elevation of 280 meters. The third specimen (UNAH 5694) was collected on 13 May 1979 at Portillo de Will (15°23'N, 85°23'W) near the Río Paulaya as it crosses the Colón-Olancho departmental border in the department of Colón at an elevation of 450 meters. The last specimen (UNAH 5706) was found on 17 May 1979 along the Río Mata de Guineo, a tributary of the Río Camalotal in the department of Colón at an approximate elevation of 400 meters.

All four specimens came from the area of eastern Honduras known as the Mosquitea in the Tropical Moist Forest formation of Holdridge (1967).

Gymnophthalamus pleei BOCOURT: AN ADDITION TO THE LIZARD FAUNA OF DOMINICA, WEST INDIES.

In 1966-67, I was a member of the Bredin-Archbold-Smithsonian Biological survey of Dominica mainly interested in the biology of *Leptodactylus fallax*. Monthly collections of the lizards *Anolis oculatus*, *Ameiva fuscata* and *Mabuya mabouya* were also made by me, Robert Gatten and Eugene Nicholls. The lizard collections were not thoroughly examined until the reproductive cycles of the three species were studied (Somma and Brooks, 1976). While examining the collection, two individuals were found that had been misidentified as *Mabuya*. These specimens were later shown to George Zug at the U.S.N.M. who identified them as *Gymnophthalamus* cf. *pleei*. In 1980, I obtained two more specimens from Dominica through the efforts of Jay Blankenship, a Peace Corps member on assignment to the Montserrat National Trust. On September 19, 1980, Ronald Crombie was able to collect seven additional specimens (U.S.N.M. 218274-218279 and U.S.N.M. 218283, a cleared and stained skeleton).

The first two specimens (CWM - 2608 and CWM - 2609; 2 April, 1966; CWM = College of William and Mary) were collected by Nicholls from the Cabrits, two small hills on a point separated from the mainland by a low, swampy area just north of the town of Portsmouth, St. John Parish. The specimens collected by Blankenship (CWM - 6651 and CWM - 6652; 19 April, 1980) were also taken in the Cabrits area. Blankenship also saw several individuals on the grounds of the Botanical Gardens in Roseau but was unable to collect any for positive identification. In both cases the lizards were found amidst litter in well drained, fairly open canopied sites similar to the habitat in which they have been found on Martinique (LeClair, 1978). All seven specimens collected by Crombie were found

Table 1. Scale counts and snout-vent lengths (mm) for *G. pleei* from Dominica.

Museum Number	Dorsal Scales	Ventral Scales	Midbody Scales	Femoral Pores	SVL
CWM— 2608	36	26	17	—	35
CWM— 2609	35	26	15	—	41
CWM— 6651	33	25	15	—	26
CWM— 6652	34	24	17	6-6	41
USNM 218174	33	25	13	—	28
USNM 218275	34	25	13	—	33
USNM 218276	35	24	13	—	28
USNM 218277	33	22	13	—	33
USNM 218278	35	24	13	—	26
USNM 218279	34	24	13	—	30

in open, grassy pasture along the banks of the Canari River, just east of the Castle Comfort Estate, St. George Parish.

Previous records of *G. pleei* are from the island of Martinique and St. Lucia (Thomas, 1965) and Guadeloupe (Schwartz, *et al.*, 1978; Crombie, personal observation, 1972). Dominica is approximately 40 km north of Martinique and 40 km south of Guadeloupe.

Pertinent scale counts and snout-vent lengths of the specimens are given in Table 1. All values, except for the number of midbody scales, fall within the range of variation found for specimens from Martinique (Thomas, 1965). Specimens from the mainland of Martinique had a mean midbody scale count of 17. Note that all of the individuals from the Canari River Valley had 13 midbody scales. The one male was reproductively mature.

As indicated above, these specimens are tentatively assigned to *pleei*. To clarify their relationship to other *Gymnophthalamus*, the entire genus is in need of revision.

I thank George Zug for his assistance and Ronald Crombie for constructive comments.

THE DISTRIBUTION AND STATUS OF *Gonatodes collaris* IN THE GALAPAGOS ARCHIPELAGO

The description of *Gonatodes collaris* by Gorman (1892) was based on two specimens collected by G. Baur at Wreck Bay on Chatham (San Cristobal) Island. Subsequent unsuccessful searches for the species at the type locality led Van Denburgh (1912) to conclude that Baur's specimens may have been mislabeled. He suggested that they might have originated from the mainland at Guayaquil where Baur had collected en route to the Galapagos. Slevin (1935), who had extensive collecting experience in the Galapagos, reiterated Van Denburgh's conclusions. Wood (1939) reestablished the presence of the species in the Galapagos with the report of a specimen from the type locality. Unaware of Wood's paper, Mertens (1963) reported the rediscovery of the species based on another specimen from the same locality. Vanzolini (1965:18) summarized the history of *G. collaris* and concluded on the basis of the type description and Merten's paper that " . . . it seems fairly safe to assume that *Gonatodes collaris* is either a strict synonym or a subspecies of *G. caudiscutatus*."

In the course of two expeditions to the Galapagos (1972 and 1974), I visited Wreck Bay where I found *Tropidurus bivittatus*, *Phyllodactylus darwini* and *P. leei* to be abundant, but not a hint of the presence of *G. collaris*. During the second trip, I visited Progreso, a small farming community situated on an elevated plateau in the humid zone some three miles inland from Wreck Bay. There I found the species to be common and obtained a series of 21 specimens (LACM 106412-32) with little difficulty. They were especially abundant in coffee groves near an abandoned sugar mill on the southeastern edge of the village.

A comparison of the color and color pattern based on specimens and Kodachrome slides of living individuals of both *G. collaris* and *G. caudiscutatus* (from coastal Ecuador, LACM 13157-58) left no doubt that the two represent the same species, as suggested by Vanzolini (1965). As such, it is the only terrestrial species of reptiles that is shared between the Galapagos and the mainland. All others are represented in the Galapagos by at least endemic species. Based on this and their apparent restriction in the Galapagos to man-modified habitats, it is likely that *G. caudiscutatus* was introduced to the island by man. The lizards could easily have been transported from the Guayaquil area concealed in shipments of nursery stock destined for Progreso. The first settlers arrived at Progreso from Guayaquil in 1869 (Slevin, 1959:106). Today there are extensive plantings of various citrus trees, avocados, bananas, coffee (and associated introduced large shade trees) and guavas. The apparent rarity of this gecko at Wreck Bay may be due to a major habitat difference. Wreck Bay is located in the dry coastal zone and with the exception of small garden plots in some yards, there is no agriculture.

The field work for this study was accomplished by joint logistical and financial cooperation of the Museum of Vertebrate Zoology and the Natural History Museum, Los Angeles during the second expedition to the Galapagos in January-February, 1974. The Janss Foundation provided most of the financial support. I sincerely thank Mary Bergen, Janet S. Dock and Dorothy Woods for valuable assistance in the field. The cooperation from the staff of the Charles Darwin Research Station, especially Peter Kramer, Tjitter De Vries and the captain, Bernhard Schreyer and crew of the *Beagle* III is gratefully acknowledged. Ing. Carlos Gonzales, Director General de Desarrollo Forestal and Jose Villa, Oficial de Conservacion, Parque Nacional Galapagos kindly provided scientific research and collecting permits.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES (Second Edition)

By Joseph T. Collins, Roger Conant, James E. Huheey, James L. Knight, Eric M. Rundquist and Hobart M. Smith

Available in summer 1982. The first edition of this reference, issued in 1978 as SSAR **Herpetological Circular** No. 7, quickly became a standard reference for herpetologists, biologists, zoos, museums, conservation organizations, wildlife societies, book publishers, and Federal and state wildlife agencies. This second, revised edition is an up-date listing over 1300 common and scientific names for species and subspecies of North American (north of Mexico) salamanders, frogs and toads, crocodilians, turtles, lizards, and snakes. New features in this edition (not in the 1978 version) are an appendix of Hawaiian amphibians and reptiles, the inclusion of the names of describers for all genera, species and subspecies, and the addition of a table comparing the number of currently recognized subspecies with those listed in earlier publications. The SSAR Committee on Common and Scientific Names (shown above) considered over 50 proposed changes for this edition, the majority of which were adopted.

TO ORDER SSAR HERPETOLOGICAL CIRCULAR NO. 12* . . . . $3.00 Payment in U.S. funds only

SEND ORDERS TO:
DR. DOUGLAS H. TAYLOR, DEPARTMENT OF ZOOLOGY, MIAMI UNIVERSITY, OXFORD, OHIO 45056 USA. Make checks payable to "SSAR;" receipt on request. A pricelist of other Society publications can be obtained on request from Dr. Taylor, including the **Journal of Herpetology, Herpetological Review, Contributions to Herpetology,** other **Herpetological Circulars, Catalogue of American Amphibians and Reptiles,** and the **Facsimile Reprints in Herpetology** series.

***Herpetological Circulars are no longer distributed free to SSAR members; individuals desiring copies of this and future numbers should place their orders as per the above instructions.**

CURRENT LITERATURE

As of March, 1978, approximately 87 researchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome. Senior author addresses that are submitted will be included. Addresses following citations are those of first authors unless otherwise noted. Citations should be sent to

REQUEST FOR INFORMATION
THE 1983 INVENTORY OF LIVE REPTILES AND AMPHIBIANS IN CAPTIVITY

I AM NOW PREPARING FOR RECEIPT OF INFORMATION CURRENT AS OF JANUARY 1, 1983. IF YOU KEEP LIVE REPTILES AND/OR AMPHIBIANS IN CAPTIVITY, AND ARE INTERESTED IN BREEDING OR KNOWING WHICH OF THE SPECIES YOU HOLD ARE IMPORTANT TO ESTABLISHING LONG TERM CAPTIVE SELF-SUSTAINING POPULATIONS, PLEASE RESPOND WITH THE INFORMATION REQUESTED IN THIS LETTER.

THE 1983 EDITION WILL BE THE SIXTH OF THESE SURVEYS AND I PLAN TO PRODUCE ONE YEARLY FOR THE NEXT SEVERAL YEARS. INFORMATION IS REQUESTED FROM ALL COLLECTIONS WORLD WIDE. IN ADDITION TO THE INVENTORY AND BREEDING INFORMATION, FUTURE PUBLICATIONS WILL INCLUDE A BIBLIOGRAPHY OF BOOKS AND ARTICLES ON BREEDING AND HUSBANDRY. GENERAL ARTICLES AND REFERENCES TO SPECIFIC SPECIES (AS WELL AS THOSE RELATING TO TEMPERATURE, LIGHT CYCLE, HIBERNATION, ETC.) ARE OF INTEREST, AND TITLES ARE REQUESTED. IT MAY TAKE MORE THAN ONE VOLUME TO BRING ALL CITATIONS UP TO DATE, BUT ULTIMATELY THIS WILL RESULT IN ONE LARGE BIBLIOGRAPHY WITH A YEARLY SUPPLEMENT TO INCLUDE NEW ARTICLES AND BOOKS. IF YOU KNOW OF ANY REFERENCES PERTAINING TO REPRODUCTION OR SPECIFIC NEEDS OF CAPTIVE REPTILES AND AMPHIBIANS, PLEASE SEND IN THE TITLE WITH THE APPROPRIATE BIBLIOGRAPHIC INFORMATION. EVERYONE IS ASKED TO CONTRIBUTE BY SENDING IN THOSE TITLES WHICH YOU FEEL HAVE HELPED YOU MOST AND WHICH WOULD BE BENEFICIAL TO OTHERS.

PLEASE SEND IN THE FOLLOWING INFORMATION, CURRENT AS OF JANUARY 1ST OF EACH YEAR, EVERY YEAR UNTIL FURTHER NOTICE:

(1) A COMPLETE INVENTORY OF ALL REPTILES AND AMPHIBIANS HELD IN YOUR COLLECTION CURRENT AS OF JANUARY 1ST. SEXES SHOULD BE INCLUDED AND CAN BE LISTED MALE/FEMALE/UNKNOWN SEX.

(2) A LIST OF ALL SPECIES WHICH BRED AND PRODUCED YOUNG DURING 1982, INCLUDING NUMBERS OF YOUNG FOR EACH SPECIES.

(3) ANY MISCELLANEOUS BREEDING INFORMATION (USE THE INFORMATION PRESENTED IN THE 1983 EDITION AS A GUIDE). INCLUDE DETAILED INFORMATION.

(4) A LISTING OF ANY PUBLICATIONS, INCLUDING BOOKS, MUSEUM BULLETINS, JOURNALS, MAGAZINES, ETC. WITH REFERENCE TO REPRODUCTION IN REPTILES AND AMPHIBIANS. REFERENCES PERTAINING TO THE CARE OF INDIVIDUAL SPECIES AS WELL AS MORE GENERAL ARTICLES RELATING TO TEMPERATURE, LIGHT CYCLE, HIBERNATION, ETC. ARE OF INTEREST.

(5) TELEPHONE INVENTORIES CANNOT BE ACCEPTED. WHEN SUBMITTING INVENTORIES GENERIC NAMES MUST BE USED; IF POSSIBLE FOLLOW THE TAXONOMIC ORDER LISTED IN THE 1982 EDITION. TYPE OR PRINT LEGIBLY AND INCLUDE YOUR COMPLETE ADDRESS AS YOU WANT IT LISTED. DEADLINE FOR RECEIPT OF INFORMATION IS MARCH 1ST.

ALL INFORMATION OR INQUIRIES SHOULD BE SENT TO:

FRANK L. SLAVENS

THE BRITISH HERPETOLOGICAL SOCIETY

The British Herpetological Society was founded in 1947 with the broad aim of catering for all aspects of interest in reptiles and amphibians. Initiated by a small number of enthusiastic and well-known naturalists, including the first president and author of the standard textbook on British herpetofauna, Dr. Malcolm Smith, the Society expanded rapidly and today enjoys national status with many international connections.

Activities of members range over a number of interrelated fields. In many cases the prime interest is in maintaining, breeding and observing various species in captivity and the Society acts as a forum for the interchange of experiences in this area. Others are concerned with the observation of animals in the wild state. There are active sub-committees which help to cater for these various tastes: the *Captive Breeding Committee* and the *Conservation Committee*. The former encourages the development of effective breeding techniques for captive specimens, thus providing animals for observation and study in vivaria, while simultaneously reducing the need to take fresh stock from wild and possibly declining populations. The Conservation Committee is actively engaged in field study, conservation management and political lobbying with a view to improving the status and future prospects for our native British species. It is the accepted authority on the conservation of reptiles and amphibians in the U.K. and has an advisory role to the Nature Conservancy Council (the statutory government body).

Meetings

About ten meetings covering a broad sphere of interests are held each year.

Publications

British Journal of Herpetology, published twice yearly, each June and December, contains papers of original research in herpetology.

British Herpetological Society Bulletin, also published each June and December, contains notices, news items, articles and original papers on all aspects of herpetology.

The Care and Breeding of Captive Reptiles, a book containing a collection of papers on recent developments in breeding reptiles in captivity. This publication is not included in members' subscriptions, but is available to members at a price of £3.00. Purchase orders should be sent to the Chairman of the Captive Breeding Committee.

Information sheets are produced on the care of reptiles and amphibians in captivity. These are continuously added to and updated.

Library

A reference library of books and journals is maintained for the use of members. The Society conducts exchanges of journals and bulletins with numerous foreign societies and institutions and in this way makes available to members a wide variety of current research, news, and general information.
